SIR,—At a meeting of all the practising doctors of the Wilmslow area it was unanimously decided to send the following resolution to the Secretary of the B.M.A. for his urgent attention.

We, the undersigned members of the B.M.A., express our entire dissatisfaction at the inadequacy of our remuneration in the N.H.S. We view the future with anxiety owing to the marked diminution in our incomes and the heavy increases in our work and expenses.

We urge you to press for the immediate revision of our terms of service.

—We are, etc.,

ROBERT BRUCE

### Salaried Service

SIR,—The gross inadequacy of the present capitation fee for those with lists under 2000 must be pressed upon the committee which is about to negotiate permanent terms of service. It should be pointed out that the number on one's list is determined by no voluntary act but entirely by an almost compulsory recruitment of the medical profession into this Service. Conditions of, for example, density of population will determine that one man will have 4,000 and another only 1,000. Such gross inequalities of income cannot be ignored.

Sliding scales of remuneration may help to smooth out some of these anomalies, but it would seem that the only satisfactory solution is the old *bête noire* of the Association—viz a salaried service. Only by this plan can numbers be distributed more equably and, similarly, hours modified in accordance with modern practices so that the medical profession may be brought into line with all other workers in the matter of a 40-hour week and payment for overtime.

It is futile to suggest that under the present inadequately paid Service we retain any of the privileges which so called freedom of service was claimed to preserve. We are servants of the State, and it is only just and fair that we should receive all the advantages enjoyed by our fellow members of a trade

union This must also refer to the so called betterment factor now assessed at the ridiculous sum of 20%, when everyone knows that there is no article or service or wages of any trade which has not jumped 100%, 200% 300%, 400%, and even 500% It is for the British Medical Association to shoulder the primary duty of any trade union—viz, to better the conditions and wages of its members—I am, etc

London N 6

W LEES TEMPLETON

### Capitation Fee

SIR—Throughout the numerous meetings that were held during the many months before July 5 remuneration was never on the agenda Nevertheless, it was generally understood that the Minister of Health had agreed to implement the Spens Report Now, Sir, is this so? Now we receive a letter from Dr Hill telling us that the capitation fee will be 17s 5d No one who lived here in 1939 and lives here now can possibly pretend that 15s 6d in 1939 is represented by 17s 5d now Surely, Sir, the present-day figure is nearer 31s? There should be no difficulty about preparing a case for revision of remuneration This is a simple issue We have a just demand Implement the Spens Report or we resign—I am etc

Bury Suffolk

P G LEVICK

SIR—I am in full agreement with Drs S T Pybus (Oct 16, p 143) and Constance F Ross (Nov 6, p 166) It is opportune that this vexed question should be discussed as early as possible with the Minister of Health How could the Government expect a State medical service to work satisfactorily if there are such disparities in earnings by various auxiliary members of the Service? The dentists and the opticians have no right to their large incomes in comparison with the average medical practitioner The medical men are the backbone of the Service and comparatively have a prior right by qualifications and learning to a fair share of the income This apparently has been overlooked by Mr Bevan I am not requesting for preferential treatment for the doctors, but as a right Could the Health Service be carried on without any doctors? Perhaps the answer is only too plain The present derogatory position of the doctors is obvious It will not be to the advantage of the Service if present conditions are permitted to continue

Capitation fee of £2 per head is a just claim, with a limitation of 2,500 patients The present financial position of many medical men is far lower than the average chemist or dentist Some are not able to meet their commitments since the initiation of the State Service The limitation of patients to 2,500 will undoubtedly help the younger and ambitious members of the profession to procure practices at an earlier date More doctors will be needed for congested areas and medical attention of patients will be of a higher standard as more time can be allotted to each patient for proper investigation

The more highly qualified members of the profession in general practice should be given the opportunity of obtaining part time hospital appointments on a reasonably paid basis This will encourage the younger members to take postgraduate qualifications with the prospect of increasing their incomes in the near future

Basic salary as it stands at the moment is no better than the means test £500 a year should be granted to all doctors (without any investigation) who have begun general practice and have less than 1,000 patients on their lists, with the proviso that each member has had two years of hospital work prior to entering in general practice This will prevent depletion of the junior hospital staff

Come on the B.M.A. Take the matter up with the Minister and let medical men get a square deal—I am etc,

SYDNEY J BELLGARD

SIR—I was interested to get a letter from Dr Charles Hill in the *Low* hard had been and still is the work of those who represent the profession I think we all appreciate this and are grateful but the 'birds-eye view' he gives of the remuneration position seems very bleak and unsatisfactory I am surprised that the *Supplement* of Oct 30 includes a 'Capitation Fee' letters only from Drs C N Cohen and J Hill (p 153) Although Dr Hill tells us that the question of the remuneration is still being considered,

a less complacent acceptance of things as they are might be advisable How are the country doctors going to live?

It is all right for Dr Hill to cite 18s or part thereof but we were led by Mr Bevan and the pundits of the B.M.A. to expect that the Spens Committee's recommended capitation fee, in terms of 1939 values would be paid Most people know what £1 won't buy to-day compared with 1939—I am etc,

Wolverhampton

W GOLDIE

### Civil Service Medical Officers

SIR—Further to my letter in the *Supplement* of Oct 9 (p 134) on representation of Civil Service medical officers and Mr Stanley Mayne's reply (*Supplement* Nov 6, p 164) on behalf of the I.P.C.S., I am indeed grateful for the assurance that something is being done by this body to bring the salary scales of the Civil Service M.O.s into line with the Spens Report There are, however, other points besides salary which concern these medical officers and with which the I.P.C.S. cannot deal for personally I did not take up medicine for the money I could get out of it any more than I joined the Services for that reason Regrettably, though the financial aspect is becoming more important to us all for very obvious reasons

I referred more particularly to those points which concern the medical profession, alone—viz, ethics and the personal management of M.O.s in the Civil Service, a subject which is considered to be surely worth serious thought if one is able to judge by the day-to-day happenings of the particular branch of the Civil Service which employs me

Finally, the mechanism of complaint of a patient with a sense of injustice the much publicized machinery of the Ministry of Health's "Complaint Department" certainly does not apply to us of the Civil Service for directly a patient feels that he has not been given exactly the treatment he himself wants he approaches his M.P., who in turn speaks to the Minister of the department concerned and an investigation is started by the Minister, thus subjecting the M.O.s of the Civil Service to a form of political oppression which can hardly be regarded as conducive to good treatment or advice I do not feel that many will disagree with me on this point, but, if the I.P.C.S. can do anything about it, it would indeed be a step forward Personally, though, like "Another Civil Service M.O." (*Supplement*, Nov 6), I feel it is more a matter for the B.M.A.—I am, etc,

CIVIL SERVICE M.O.

### Independence of Government

SIR,—The concession wrested from the Minister of Health which overnight caused such a change of heart among our representatives that they recommended a further plebiscite and acceptance, can now be seen for the hollow and worthless thing it is Apart from the fact that it made no attempt to ensure a fair income for doctors, it was an arrangement whereby the logical claimants of the basic salary may be conceded their rights only if the recipients of larger incomes are willing to sacrifice a proportion of their earnings

Going one better than the British Medical Association and the Minister, the local executive councils on their own initiative introduce as a condition to qualify for the basic salary that the claimant's professional income *plus his income from other sources* must show a diminution Vichy and its satellites did not do better for Hitler Once we ourselves introduce the principle that our professional income may be reduced if we have any other source of income there will be no limit to what others will impose upon us Can anyone conceive this Government daring to apply this principle to the consideration of the minimum wage of dockers and mine-workers—as for example the income from the wife's charring, subletting of the back room sale of eggs etc?

We can never expect a Government to pay us adequately This one will not—the Prime Minister himself broadcast that we were now adequately paid—and no Government has paid well in the past This counting of heads is an evil method reacting badly on doctor and patients particularly in the largest panels, where either a doctor attempts the impossible and ruins his health or he preserves his sanity and health by insufficient attention to his patients

We can and we must achieve complete independence of the Government as in socialist France and New Zealand. The public will be our private patients and a necessitous section who will make a weekly contribution will be partially reimbursed by the Government for their doctors' fees. It is essential that the patient pays something to prevent unjustified cills on the doctor and mounting national drug bills. Those who sit back saying 'You can't put the clock back' etc. but nevertheless remain in a state of chronic irritation deserve to stew in their own juice. Those representatives who are suffering from such a rigidity of mind that they cannot conceive an alternative to the present system or are too defeatist to fight for one should give way to others more vigorous.

Within two years there will be a general election. We know that the Socialists are out to crush us as members of a privileged professional class while the Minister regards us with lifelong venom. If we wish for the support of the Opposition to reform the situation we must enlist it now by enlightenment and active approach. The Opposition has demonstrated its intention to unscramble the egg if the Steel Bill becomes law, and modifications such as those above mentioned can be made in the National Health Service. Not one of us has had a pennyworth of compensation yet nor knows what he will get. We have the ear of the public if we bestir ourselves, and the Opposition can and should be made to realize the value of our support—I am etc.

Bournemouth

A. R. THATCHER

### Superannuation

SIR—The paragraph (*Supplement* Oct 23 p 146) of Dr Charles Hill's letter dealing with superannuation brings cold comfort to any doctor over 55 years of age. It is quite clear that no doctor over that age can get 10 years contributions in before he is 65 so that none in this category can qualify for a pension. This is an aspect of the matter that should again receive the urgent consideration of the Association when the remuneration of doctors over the entire field covered by the Act comes under review, as it surely must in the near future.

The present Health Act is merely an extension of the old National Health Insurance Act, under which many had worked since 1912. A considerable number of patients came under these old Acts. These people are receiving precisely the same medical attention certificates etc., as under the new Act. Surely it is common justice that doctors should be allowed to count for superannuation purposes that proportion of these patients who have always been panel patients. In most practices this is rather more than half that of the entire practice, so that they should be allowed to count at least half, and probably more, of their years of service given to this class of patient towards a pension. This period, or whatever is considered to be an equitable one, should be added to any years of service given under the new Act. I hope all doctors over 55 years of age who are personally concerned with this matter will take it up with the Association and the Ministry with vigour—I am etc.

ROBERT ELLIS

Chairman Cambs Local Medical Committee

\* \* A doctor who is on an executive council list may apply at any time between the age of 60 and 65 for an extension of pensionable age up to but not beyond the age of 70. The extension allows a practitioner of 59 years of age on entry to put in the 10 years service required to qualify for a pension on retirement at or after age 69—ED B.M.J.

### The Winchester Memorandum

SIR—In connexion with the recent publication of the Winchester Division's Memorandum on the Reorganization of the B.M.A. it will be of interest to other Divisions to know that two representatives from this Division have been asked to attend the Organization Committee's meeting on Dec 21.

Although we in this Division know that our Memorandum has been discussed at a recent meeting of the Organization Committee, and that it is on the agenda for the meeting of Council on Oct 27, we have been disturbed to note that to date no indication whatever has been given to our colleagues that the Memorandum has even been noticed by Council. Since one of the points we make is that much goes on behind

the scenes' of which the profession as a whole is kept in ignorance we should like to make use of your column to request that publication should be given to each stage of Council's consideration of this Memorandum containing as it does matters vitally important to all members of the profession and being as it has proved to be a subject of great interest to Divisions—I am, etc.

RONALD GIBSON  
Hon. Secretary Winchester Division

\* \* The Memorandum was referred to in the report of the Proceedings of Council (Nov 5 p 157)—ED B.M.J.

### Delayed Payment

SIR—May I add another two protests to the growing number that appear in your columns weekly *re* the finance of the National Health Service? My first protest is about the compulsory loan to the Government that is levied on every doctor under the present quarterly method of payment. Let us assume for simplicity of calculation that Dr Jones receives £300 per quarter from his executive council. This represents £100 per month for work completed. Thus at present he lends the following sums to the Government: £100 for two months and £100 for one month. Take the interest on these amounts at 2½% per annum, and we find he has lost £125 × 2½% = 3½ plus 2½ × 1/4 per quarter = 3/8 per annum = £2 10s. Multiply this figure according to the multiples of £300 per quarter received by all practitioners taking part, and one finds that the medical profession is lending the Government some figure between £30,000 and £60,000 per annum free of interest.

Even the War Office managed to pay monthly after deduction of income tax and credit of all sorts of special allowances. In addition, one could always draw a certain proportion of one's pay when required. I can see no reason for this time lag in payment being perpetuated and consider that the medical profession should press for prompt payment for work done.

My second protest is on similar lines. Like several thousand other practitioners I have done some midwifery since July 5. I have sent in claims two months ago and am now calmly informed by my executive council that 'these claims are acknowledged and payment will be made in due course.' If I treated my butcher in the same way I should go very hungry next week end.

In the old days of private practice I adjusted my fees to cover a certain delay in payment. If for so called 'difficulties of administration' it is stated to be impossible to pay promptly which view I do not support, let us at least receive interest to compensate for these delays—I am etc.,

Harrow, Middlesex

J. F. S. STEPHENS

### Justification for Basic Salary

SIR—It is very discouraging at the beginning of the Health Service to find a great change of attitude occurring within a few months. Originally the basic salary was to be for every one, the B.M.A. opposed this on the grounds that it was making doctors Civil Servants. Following negotiations the Minister granted a concession to the profession that if a doctor wished he need not accept the £300 basic salary, and he so arranged the remuneration that those with more than 2,200 on their list were better off without it. Most of the profession were quite satisfied with this decision—the B.M.A. had won their point. Most doctors with less than 2,200 on their list applied for the basic salary, and were regarding their application as being quite just. If the basic salary is granted to an applicant the doctors in the 2,200 plus class are slightly less well off than if the basic salary is refused to as many as possible. 80% of the applicants in my particular county were refused, and judging from the Press reports similar decisions were taken by executive councils throughout the country.

At present the directions published through this *Journal* seem to conflict with its quotations of the Minister's interpretation of the Act. He states that consent *ought* to be given where there is reasonable justification which he follows by five examples, the only regulation that exists is that if a person after two years has less than the minimum number of patients on his list he is not entitled to the £300 basic salary, but even then he may receive some basic salary being less than £300 in amount. There is no mention of having to prove extreme hardship in the Minister's interpretation.

The amount of money a person gains by being given the £300 salary may amount to 20% of his income, and the amount a person above 2 200 loses by his colleagues' getting the £300 is unlikely to exceed 5% of his income. Therefore the person that stands to lose most is the person in the lower-income group. This is very unjust, and a great split in the profession is bound to arise from the present confusion.

The B.M.A. has made a great stand for the freedom of the profession. In future it is likely that another great stand will have to be made for an adequate remuneration for its members. I therefore feel that it is important that the rent caused in our ranks should be closed so that once more we are united. The only way this can be done is for the Minister to be more explicit on the way basic salary should be distributed. Are the poor going to receive from the rich or the rich from the poor?—I am, etc

Llangefni, Anglesey

J. H. HUGHES

## POINTS FROM LETTERS

### Ludicrous Situation

Dr JOHN V. MAINPRISE (Holcombe Rogus, Somerset) writes: The new Health Service has been in force now for four months, and one can now begin to see the shape of things to come. As a profession we have shown a most unfortunate lack of political and business instinct, our vital "principles" have been thrown away and no policy seems to have taken their place. On all hands we are asking, *Quo vadis?* As the Act is now a *fait accompli* and is in full operation it is useless to bemoan our lost opportunities. We now face the ludicrous situation that we have been working a service for months and have not yet been told what pay we shall finally have, let alone the amount of compensation for our practices that we shall receive. The plain truth is that the astute politicians have put one over us.

Doctors in congested industrial districts will find a perfectly adequate income, but under what conditions? I have just returned from a holiday in the North and find evidence of grave unrest among my colleagues. They dread the winter and fear that many of the older men will not survive the strain. This is no far-fetched idea. It is obvious that many doctors will either give a rushed inefficient service or else will collapse under the strain. The public are already showing a marked alacrity to avail themselves of the facilities offered, and surgeries are now far busier than ever before the Act. The rural doctors are in a much worse plight, as their very standard of living is threatened. Practices in scattered areas that previously produced a reasonable income are now producing a net income, after deducting expenses, that would not thrill a good bricklayer.

While there is yet time I would appeal to the Minister to remove from us all the strain of financial worries and give an adequate capitation fee with limitation of lists so that the quality of our work may be kept up. Locums should be provided for holidays, and country partnerships should be allowed mileage reckoned on the distance of the patients from the doctor of their choice, not from the nearest partner.

### Immediate Cash Advance

Dr J. L. McCALLUM (London, W.C.1) writes: The purpose of the Association and its officers at the moment is to secure the best conditions of service for those of its members who have been foolish enough to entrust themselves to the tender mercies of the Minister of Health and his satellites without adequate legal safeguards. It is no good telling a general practitioner with a list of 2,000 patients to carry on his business and provide adequate medical care for these patients for six months to a year on capital which he may or may not possess (but which would have to be in the region of £600-£1,000 to cover all his running expenses) on the promise of getting his year's income already reduced, by next July. Most of us having left the Services and being heavily committed with repayment of loans, rent, families, equipment, etc., have no capital with which to support ourselves till our new masters care to pay us. The position is desperate and neither the B.M.A. nor the Ministry has foreseen the contingency. The Secretary of the B.M.A. has sent a circular letter to the profession in which he counsels patience and seemingly supports the Ministry. May we ask, Sir, what we are to be patient on? The bank? We must have an immediate advance, cash down, equal in value at the least to the basic salary. Adjustments can be made later at Government expense, not ours. Previous to July 5, 1948, we could manage during the difficult early days because a large portion of the money in any practice was either paid in cash at the time or in easily collected amounts. If we were now being paid by piece rates we should all be earning double owing to the increased number of attendances but as things stand we are worse off in every direction, and we shall never get clear if we are to continue to be paid advances on account three months in arrears.

## H.M. Forces Appointments

### REGULAR ARMY EMERGENCY COMMISSIONS

#### ROYAL ARMY MEDICAL CORPS

War Substantive Major A. R. Madden has relinquished his commission and has been granted the honorary rank of Lieutenant Colonel.

War Substantive Captain E. T. Anderton has relinquished his commission and has been granted the honorary rank of Major.

War Substantive Captain N. V. Sapier has relinquished his commission on account of disability and has been granted the honorary rank of Captain.

Lieutenants P. Baer, G. B. Brown, C. F. Bunting, W. W. Campbell, A. A. Chazan, O. G. Dodge, K. C. Grigor, J. Guthrie, H. G. Hanley, L. A. Humphrey, H. G. Mather, J. McCreadie, C. Nolan, A. E. Preston, D. R. V. Prys Jones, R. Randall, B. O. Scott, K. S. Shaw, B. Steinberg, A. B. Watson, J. C. Walker, T. G. E. White and E. Woolf to be Captains.

#### WOMEN'S FORCES

#### EMPLOYED WITH THE R.A.M.C.

War Substantive Captain C. L. Hess has relinquished her commission and has been granted the honorary rank of Captain.

## Association Notices

### NATHANIEL BISHOP HARMAN PRIZE

The Council of the British Medical Association is prepared to consider the award of the Nathaniel Bishop Harman Prize in the year 1949. The value of the prize is approximately £100. The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has been previously published in the medical press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1949 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

The writer of the prize-winning essay may be required to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association. Each essay must be typewritten or printed in the English language, and must be distinguished by a title and a motto. The essay must not bear the name of the writer, which should be sent with the essay in a sealed envelope bearing only the motto on the outside.

Essays must be forwarded to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than March 31, 1949. The title of the proposed essay and the motto should also be notified in writing to the Secretary by Dec. 1, 1948, and should not be accompanied by the writer's name. The prize will be awarded at the Annual Meeting of the Association to be held in 1949. Inquiries relative to the prize should be addressed to the Secretary.

### SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for research scholarships as follows: An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1, 1949. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole

of his or her time to the work of research but may hold an appointment at a university medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition applications are invited for the award of the Insole Scholarship of the value of £250 for research into the causes and cure of venereal disease.

Applications for scholarships must be made not later than March 31, 1949, on the prescribed form a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

### PRIZES FOR MEDICAL STUDENTS

The Council of the British Medical Association is prepared to consider the award in 1949 of prizes to medical students for essays submitted in open competition. The subject of the essays for 1949 shall be "The Value of Observation in the Training of the Medical Student." The purpose of these prizes is the promotion of systematic observation among medical students. In awarding the prizes *due regard will be given to evidence of personal observation*. No study or essay that has previously been published in the medical press or elsewhere will be considered eligible for a prize.

The following prizes are offered:

**National Prizes**—six, each of the value of £25.

**Regional Prizes**—as detailed below, based on the four Regions of the British Medical Students Association.

London Region, 6 prizes (1 of the value of £15, 5 of the value of £7).

Midland Region, 3 prizes (1 of the value of £15, 2 of the value of £7).

Northern Region, 3 prizes (1 of the value of £15, 2 of the value of £7).

Scottish Region, 5 prizes (1 of the value of £15, 4 of the value of £7).

Any medical student who is a registered member of a medical school in Great Britain or Northern Ireland at the time of submission of the essay is eligible to compete for the prizes. The winners of the National Prizes will be ineligible for the award of a Regional Prize. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final. Should the Council of the Association decide that no essay entered is of sufficient merit, no awards shall be made.

Each essay must be typewritten or written legibly in the English language, and must be unsigned and accompanied by a detachable sheet giving the name of the candidate, his medical school, and his B.M.S.A. Region. Essays must be forwarded so as to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than March 31, 1949.

### PRIZES FOR NURSES

The Council of the British Medical Association is prepared to consider the award in 1949 of three prizes each of the value of 20 guineas for the best essay and three prizes each of the value of 10 guineas for the second best essay submitted in open competition by each of the following categories of nurses: (i) Pupil nurses; (ii) State registered nurses working in a hospital; (iii) State registered nurses not working in a hospital—i.e., district nurses, private nurses, etc.

The subjects of the essays for 1949 shall be: category (i), "What discipline do you think necessary in the training of nurses?"; category (ii), "What part of nursing duties can be delegated to others with safety?"; category (iii), "The care of old people in their own homes."

The purpose of these prizes is the promotion of systematic observation among nurses. In awarding the prizes *due regard will be given to evidence of personal observation*. No essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Nurses who are undergoing training at a hospital are eligible to compete under category (i), nurses registered by the General Nursing Council are eligible to compete under categories (ii) and (iii). If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. Should the Council decide that no essay entered is of sufficient merit, no award shall be made. Each essay must be typewritten or legibly written must be unsigned and must have attached to it a sealed envelope containing the name and address of the candidate and the category into which he or she falls. Essays must reach the Secretary of the British Medical Association not later than March 31, 1949. Inquiries about the prize should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

## NOTICE TO SHIP SURGEONS

### BRITISH MEDICAL ASSOCIATION SHIP SURGEONS SUBCOMMITTEE

The General Practice Committee of the British Medical Association has reappointed for the current session a subcommittee to consider matters affecting the interests of ship surgeons.

The Subcommittee will hold its first meeting of the session at B.M.A. House, Tavistock Square, W.C.1, on Tuesday Nov. 23 at 11 a.m., and any doctors in active practice as ship surgeons who find it convenient to attend are invited to do so if possible giving notice by letter or telephone of their intention to come.

CHARLES HILL  
Secretary

### A PROPOSED SUTTON COLDFIELD DIVISION

Notice is hereby given by the Council of a proposal to form a Sutton Coldfield Division of the Birmingham Branch, the area of the new Division to comprise the Municipal Borough of Sutton Coldfield.

Any member affected by this proposal and objecting thereto should write to the Secretary of the Association not later than Dec. 18, 1948.

CHARLES HILL  
Secretary

### Diary of Central Meetings

DECEMBER

3 Fri. Publishing Subcommittee 11 a.m.

### Branch and Division Meetings to be Held

**DARTFORD DIVISION**—At West Hill Hospital, Dartford, Thursday Nov. 25, 8.45 p.m. Programme: Film on Post partum Haemorrhage, followed by lecture and discussion. Lecturer: Mr. Keith Vartan.

**EAST HERTS DIVISION**—At County Hospital, Hertford, Thursday Nov. 25, 9 p.m. Address by Mr. O. S. Tubbs "The Advances in Thoracic Surgery During the Last Decade."

**LEWISHAM DIVISION**—At Lewisham Hospital, 390, High Street, London, S.E., Sunday, Nov. 21, 10.30 a.m. Clinical meeting.

**OXFORD DIVISION**—At Radcliffe Infirmary, Oxford, Wednesday, Nov. 24, Annual general meeting. Election of Officers 1948-9 etc.

**SALISBURY DIVISION**—At Cathedral Hotel, Salisbury, Wednesday, Nov. 24, 8 p.m. Discussion "Treatment of Peptic Ulcers with Special Reference to Haematemesis." To be opened by Dr. R. G. M. Longridge.

**SUNDERLAND DIVISION**—At Sunderland Royal Infirmary, Thursday, Nov. 25, 3 p.m. Annual address by Mr. A. Dickson Wright (London) "Surgery of the Blood Vessels." 7.30 p.m. Annual dinner.

**WEST MIDDLESEX DIVISION**—At Town Hall, Ealing, Friday, Nov. 26, 9 p.m. Frank Stephan, Ph.D. "Atomic Energy."

**WINCHESTER DIVISION**—At Royal Hants County Hospital, Winchester, Saturday, Nov. 20, 2.30 p.m. Agenda: Consideration of Resolutions from Huddersfield and West Sussex Divisions; Capitation Fee; Consideration of Winchester Memorandum etc.

### Meetings of Branches and Divisions

#### PRESTON DIVISION

The annual B.M.A. lecture was delivered at Preston Royal Infirmary on Nov. 9 by Professor R. McWhirter. The chair was occupied by Dr. A. R. Grant, chairman of the Division and the was a large and appreciative audience. The subject was "Some Observations on the Spread of Malignant Disease" and Professor McWhirter discussed the modes of spread of all the principal types of malignant disease. One interesting observation was the increase in incidence of early metastases where movement or handling of the primary growth occurred. This has been shown experimentally in malignant disease in mice and a parallel was drawn between the incidence of malignancy in the hard and soft palate. His lecture was illustrated by many excellent slides. A number of questions were asked and in replying Professor McWhirter dealt with other aspects of his subject. A vote of thanks, moved by Dr. A. Gibb, was seconded by Dr. A. E. Rayner, former radiologist to the Preston Royal Infirmary, was passed with acclamation.

#### TUNBRIDGE WELLS DIVISION

A B.M.A. Week end Refresher Course was held at Tunbridge Wells on Oct. 23-24 when the following lectures were given: Mr. J. Yates Bell, "The General Practitioner and the Kidney Tract"; R. D. Lawrence, "Diabetes"; Sir Herbert Eason, "What the Doctor Should Not Do"; Dr. Waller, "Modern Approach to Breast Feeding"; Mr. A. Dickson Wright, "Varicose Veins and their Treatment"; Sir Robert Young, "The Chest"; Sir Harry Sanders, "The After effects of Tropical Diseases."

## "TOWARDS A LOWER PAEDIATRIC MORTALITY"

BY

WILFRID GAISFORD, MD, FRCP

*Professor of Child Health University of Manchester*

Although much progress has been made in paediatrics in the past thirty years a great deal yet remains to be done. Repeated reference has been made to the divergence of the curves showing the fall in infant and neonatal mortality rates respectively. There is no doubt about the improvement in the infant mortality rate—a drop from 105 per 1,000 in 1910 to 45.5 per 1,000 in 1944 is certainly significant. Yet for neonates (i.e., in the first month of life) the lag is pronounced—from 38 in 1910 only to 24.5 in 1944. This is partly to be explained by the number of congenital abnormalities which cannot at present be prevented, but also by a big loss of premature infants which could be reduced by stricter attention to antenatal diet and by better immediate post-natal care.

In childhood generally improvement has been steady. Increased interest in paediatrics and especially in prophylactic paediatrics, better nursing care, more health education, smaller families, priorities in food and milk, and the Government issue of free vitamins have all helped. In addition certain specific factors have also helped—for example, the chemotherapeutic drugs and antibiotics, intensive immunization campaigns, and a natural decrease in virulence in certain organisms, notably the scarlet fever streptococcus. Extensions of the immunization programmes may still further improve matters in the future.

Methods of lowering the mortality rate during infancy and childhood may be considered from three aspects—antenatal, neonatal, and post-natal.

### Antenatal Paediatrics

The term antenatal paediatrics was introduced by Sir Leonard Parsons in his Blair Bell Lecture to the Royal College of Obstetricians and Gynaecologists in 1945. This lecture provided an immense stimulus to paediatricians throughout the country.

The significance of virus infections in early pregnancy and their relationship to congenital malformations seem now definitely confirmed. The work on the rhesus factor is another example of modern research. From the region supplied by the North-Western Blood Transfusion Service there are approximately 150 Rh-negative pregnant women (with anomalous agglutinins in the serum) every year, and it is hoped to devote a ward specially to the immediate post-natal care of the infants born of these women. The problem may, however, be tackled antenatally—assuming a routine testing to be, as it should, universal. Every female should be tested early in life and careful note taken of those found to be Rh-negative—lest a blood transfusion

should ever be necessary and sensitization result from the use of Rh-positive blood, with consequent danger of producing an affected infant from pregnancy in later life. Diamond has shown that such infants are the most severely affected.

Two possible methods of attack have been suggested, both in the experimental stage at present: (1) chemical prevention of the antigen-antibody reaction, and (2) immunological inhibition of antibody formation. TAB injections have been employed for the latter—without success so far; neutralization of maternal antibody has been attempted by Kariber and Miller (1947) using ethylene disulphonate, giving weekly injections during the last half of pregnancy, with suggestively satisfactory results in their first few cases.

There is no doubt that research on these prophylactic lines offers more hope than the present methods of treating the infants after birth, even with replacement transfusions, for nothing can be more disheartening than hours of work spent in transfusing a yellow baby only to find subsequently that a kernicterus already present but unsuspected at birth results ultimately in a mentally defective child. Nevertheless improvement in the prognosis generally has undoubtedly occurred following adequate treatment. The mortality was formerly something over 50%, since the introduction of Rh-negative blood transfusion it has dropped to something like 30%, and with improvements in the technique of replacement transfusions immediately after birth it may be expected to show a further fall.

### The Neonatal Period

Prematurity is still one of the major causes of neonatal death, and, although the cause of prematurity is still undiscovered in something like 50% of cases, it is known that diet is a matter of outstanding importance in preventing it. Antonov (1947) found that 50% of the births in Leningrad during the siege in 1941 were premature, and that the mothers produced less breast milk and that it lasted for a shorter time. He also noted that mastitis neonatorum—the swelling of the breasts in the newborn that is so common and usually betokens a plentiful milk supply—occurred in only 2% of the infants.

The Australian discovery, reported by Gregg in 1941, of the relationship of German measles in early pregnancy to congenital abnormalities has opened up a large field of inquiry into a hitherto completely obscure subject. The possibility that other infections than rubella—e.g., mumps, influenza, and herpes—may be aetiological is probable, and other deformities than malformation of the heart and eyes may subsequently prove to be related to such infections. If

\*Abridged from a lecture given to the Halifax Division of the British Medical Association on March 24, 1948.

allowance be made for the incubation period and for the time taken by the virus to penetrate the placental barrier the actual maternal infection may be placed earlier than the fifth week.

The logical sequel to this knowledge is, of course, that every precaution should be taken to prevent such infections in pregnancy, either by ensuring that they have already taken place earlier in life—e.g., by deliberate exposure in childhood, due care being taken that the child's general condition is satisfactory—or by the rigorous avoidance of exposure during the first three months of pregnancy, or by the administration of gamma globulin if exposure has occurred at this time. Unfortunately the efficacy of gamma globulin in preventing rubella is by no means certain.

### The Post-natal Period

It has been generally accepted that newborn infants and infants under three months of age are poor antibody producers and that there is no great point, therefore, in attempts at early active immunization. Recent work by Sako *et al.* (1945) has cast doubts on the truth of the accepted findings, and early immunization may prove to be effective to some extent at any rate. For example, Waddell and L'Engle (1946) immunized 129 infants with pertussis vaccine at one week, one month, and two months after birth, and 70% showed an adequate response. Controls showed no carry-over from the mother.

The site of antibody formation is still a matter of dispute, but if, as Harris and his co-workers (1945) hold, one of the chief sites is the lymphocyte then there is no reason why newborn infants should not produce antibodies, as they normally have 66% of their total white cells in the form of lymphocytes after the first week of life, and gamma globulin is one of the constituents of the lymphocyte. Nevertheless, such immunity takes time to develop. For example, whooping-cough immunity certainly requires two months. Whooping-cough is not common in the first few months of life, yet when it does occur it is fatal in a large percentage of cases (686 infants under a year old died from whooping-cough in 1944 in England and Wales). Diphtheria is also a fatal illness in infants but it is much rarer.

The idea of immunizing the mother during the later months of pregnancy so that the immunity may be carried over to the infant to last him until such time as active immunization may be capable of carrying on the immunity is well worth considering. It has already been done on a small scale in America by Cohen and Scadron (1943) and was found to be harmless to the mother and child and to result in a reasonable titre in the infant's blood in the first months of life. Similarly, immunization of Schick-positive pregnant women might be a worthwhile procedure. Schick-negative women produce Schick-negative infants, who would not need immunizing immediately.

Cohen (1947) has drawn attention to the altered immunity in adult populations as a result of mass inoculations. 85% of adults were immune to diphtheria in 1920—only 50% are now, owing to the loss of artificially acquired immunity from the lessened chances of exposure. This affects the newborn also, who in 50% of cases may thus get no carry-over from the mother. Similarly, a high proportion of adults are not immune to whooping-cough and therefore their babies are susceptible.

Close collaboration between obstetricians and paediatricians is the first requisite in reducing neonatal mortality. We all realize that not every infant can be born at full term, and one of the most important problems is how to deal with premature infants.

### Nursing

The most important factor in saving the lives of the infants is nursing. A good gamp in a humble cottage is better than a poor nurse in the most up-to-date prematorium. As is well known, most premature infants who die do so in the first 48 hours, and very often death occurs shortly after a feed. There is a tendency to atelectasis, the swallowing reflex is poorly developed and feeds are easily regurgitated and inhaled. Clement Smith of Boston, gives no fluids at all to premature infants for two to four days after birth. By that time they have got over the shock of birth, their lungs are expanding, and their swallowing reflex is less immature. I have tried this technique for the past six months and the results have been most satisfactory. It is little short of amazing to find that a 2½-lb (1.13 kg) baby will go for between 70 and 80 hours without fluids of any sort and yet do very well. Weight loss is not excessive. Feeding, when it is started, is a less precarious procedure, and subsequent progress is most satisfactory. Oedema is lost more quickly. The infants are kept warm, given oxygen, and left completely alone except for changing until they indicate by their cry that they are hungry, this crying also expands their lungs. Jaffe (1948) has reported on the progress of infants so treated in the premature station at St. Mary's Hospital.

The question of the advisability of giving vitamin K in all cases, either to the mothers just before labour commences or to the infants at birth, is still debated. Some give it as a routine, others only in cases of difficult delivery where cerebral haemorrhage may be expected, while others reserve it solely for infants who have already bled (i.e., cases of melaena neonatorum). As it is perfectly harmless and it is difficult to judge in any given case whether there will be a hypoprothrombinaemia of pathological intensity or not, it should always be given. Another reason is the possibility of preventing a subdural haematoma from slowly accumulating—giving rise to convulsions later and involving, if diagnosed, surgical evacuation of the clot. Such haematomata are often found at necropsy, and have undoubtedly been the cause of death.

Kerpel-Fronius (1948) has suggested that vitamin P should be given as well, that there are two factors concerned with the diathesis—one the hypoprothrombin aemia and the other an increased capillary fragility—both resulting from vitamin deficiency in the mother's diet. The seasonal incidence has of course been known for a long time, which adds some weight to this theory.

Another frequent cause of death is infection. This too is often unrecognized, being rapid both in onset and in spread, and terminating fatally perhaps within 24 hours. Because of the frequency of *Bact. coli* and other Gram-negative organisms—some not generally pathogenic in later life—streptomycin may well come to be the drug of choice in treating such cases. Short intensive treatment is all that is needed, so there should be no question of drug fastness as in the treatment of tuberculosis.

As the tendency is for more and more women to go into hospital to have their babies the question of nurseries in maternity wards is an interesting and still undecided problem. The advantages of having mother and infant together are obvious, yet comparatively few hospitals make such arrangements. I have made a point of asking mothers in the maternity wards I have visited whether they would like their babies in a cot within reachable distance all the time or whether they would prefer them in a nursery and just brought in for feeds. Their replies have been fairly consistent: the primiparae would like their infants with them, the multiparae prefer a nursery. This is just what is wanted really—the primipara to be taught how to feed and change

and wash her infant, and instructed in the various difficulties to be overcome in breast-feeding, and the multipara to have a well earned rest. In other words, our new maternity hospitals might well provide special wards for primiparae, each bed having a cot attached, with only a small nursery for the occasional use of a fractious infant who would need to be put out for a night or two, and wards for multiparae as at present, associated with a regular nursery for all their infants.

There is a great need for accommodation for infants born of tuberculous mothers so that they may be removed from "open" contact. The provision of tuberculosis-free foster-homes is the ideal solution: there is less risk of cross-infection than in an institution for babies. Even when BCG vaccination is undertaken on a large scale such accommodation will still be necessary, though for a shorter period of time.

The infant of a diabetic mother may have an urgent need of glucose immediately after birth, and preparations should be on hand to meet this need. Although newborn infants are comparatively insusceptible to hypoglycaemia (blood-sugar levels of 50 mg per 100 ml are common in normal infants) the hypertrophy of the islets brought about by the foetal hyperglycaemia may occasionally cause severe symptoms. The very sudden drop in blood sugar which these infants may undergo may easily result in death from hypoglycaemia, yet they may all be saved by prompt treatment. As the infants who manifest these changes are usually large—indeed, over large—the glucose can be given quite adequately by mouth, but if necessary gavage should be used, either intermittently or by continuous drip through a catheter passed into and left in the stomach, or in extreme urgency intravenous injection may be necessary. An essential prophylactic measure is the careful control of the mother's blood sugar during pregnancy.

After the neonatal period the reduction in mortality becomes more and more a preventive programme, the stress being on child health rather than on curative paediatrics, for, though research into curative methods—especially new chemotherapeutic agents and antibiotics—goes on, a distressingly large number of infant and child deaths are due to preventable conditions.

### Preventable Diseases

As Davison (1934) has pointed out, of the 100 important diseases which may attack a child 37 are preventable, and these 37 cause more than half the deaths in childhood.

Active immunization has been responsible for a considerable reduction in the death rate in childhood, especially from diphtheria. Every child should have adequate immunization against diphtheria, smallpox, and whooping-cough, and, if he lives in the country, typhoid and tetanus as well. Furthermore, boosting doses should be given at intervals: the rise in antibody titre is both prompt and high after even minute doses—e.g., 0.1 ml given intradermally. The fact that two or three antigens may be combined with advantage is helpful and reduces the total number of injections necessary: diphtheria and pertussis go well together, so do typhoid and tetanus. When gamma globulin becomes generally available we may have another potent agent against infection.

Deaths from tuberculosis in infancy are still far too numerous. They may be prevented by (a) prevention of exposure as, for example, by the use of foster-homes for infants born into homes where there is "open" tuberculosis; (b) by setting up "preventoria" where children entering from primary infection may be watched till the first three months after their primary infection, which are vital prognostically, have been successfully passed,

(c) by BCG or Wells's vole-bacillus vaccination, or (d) by not allowing milk that can possibly contain tubercle bacilli to be given to any infant or young child—a point of practical importance which could and should be tackled immediately.

The percentage of cases of tuberculous meningitis which is bovine in origin doubtless varies geographically, but it is by no means negligible—and all could and should be prevented. The Animals' Bill is a big step forward. The Minister of Agriculture reported (*BMJ*, 1948, 1, 371) that even to-day nearly seven-eighths of the cattle population in Great Britain were not attested and that it would take from ten to fifteen years to clear the country of bovine tuberculosis. Till then compulsory adequate pasteurization would help enormously with our problem.

Rickets was a disease which indirectly caused many deaths every year. The fact that a case of florid rickets is now hard to find is a triumph of preventive paediatrics largely due to public-health work and education. The full value of this improvement will not be appreciated till the next generation of infants is born—of women without rachitic pelvises.

### Advances in Surgery

The amazing advances in cardiac and thoracic surgery provide a contrast: here curative treatment has indeed advanced by leaps and bounds. The names of Blalock and Ladd and Gross have added lustre to the list of brilliant pioneer surgeons. No recovery from oesophageal atresia or tracheo-oesophageal fistula had ever occurred before 1939, now there are several such reported. Swenson (1948) has recorded 57 survivals out of 113 operations. The mortality in congenital diaphragmatic hernia has dropped by 60% in the last fifteen years, and the prognosis in certain types of congenital heart disease and in bronchiectasis has been materially improved. As Ladd (1948) says, the treatment of congenital anomalies may be expected to advance even more rapidly during the next few decades.

Appendicitis—or, rather, peritonitis resulting from delayed diagnosis of acute appendicitis—is still responsible for a formidable number of deaths every year. It occurs at all ages, and unfortunately with the most equivocal signs and symptoms in the youngest infants, when the diagnosis indeed is often not considered. The differential diagnosis of the acute abdomen is a matter calling for clinical acumen of the highest degree, but I am quite sure that in any case of doubt the correct thing is to play for safety by doing a laparotomy.

And what can one say about deaths from road accidents? Though hardly a paediatric problem, it certainly has repercussions that sadden paediatricians as much as everyone else. In 1945, 1,540 school-children were killed in accidents in England and Wales—651 of them on the road. It is a depressing thought, and one that should come home to doctors who are allowed adequate petrol to keep their cars on the road, that one of the advantages of the abolition of the basic petrol ration has been a lowering of the death rate among children from motor accidents.

### Conclusion

Research is constantly proceeding all over the world in the wards of hospitals, in laboratories, and in the field; workers of all sorts are engaged on curative and prophylactic problems alike, and many of their puzzles will be solved in due course—doubtless to be replaced by others again in their turn to be solved. As soon as we get an effective bactericidal agent up crops the resistant strain; as soon as we immunize infants we get a susceptible adult population; as soon as we find the cause of a group of diseases and their specific treatment a new organism

pp. 1-10 the virus, still awaiting a virucide Nature evidently abhors not only a vacuum but stasis also. In paediatrics particularly it is necessary to avoid stasis, for example, the static infant soon becomes marantic and the marantic infant dies. That is what we have to prevent. There should be no such thing as marantic infants needing cure—they should be so cared for that the causes are prevented. Prophylactic and curative paediatrics must advance together hand in hand if real child health is to be achieved.

## TEMPERATURE RECORDING IN SICK CHILDREN

BY

ALAN MONCRIEFF, M.D., F.R.C.P.

AND

B. J. HUSSEY, M.R.C.S., L.R.C.P.

(From the Institute of Child Health, University of London and the Hospital for Sick Children, Great Ormond Street)

The temperature curve of a sick child is regarded as an essential observation in estimating, for example, the presence or persistence of infection, and a rise above normal in healthy children may be the earliest sign of an infectious malady such as measles or poliomyelitis. This being so, the means of estimating the temperature is obviously of great importance and the definition of "normal" requires careful consideration. Several curious and anomalous temperature curves prompted the small inquiry reported here, which, although it possibly raises more problems than it solves, may serve to stimulate others to larger surveys.

The standard methods of temperature-taking in children in Great Britain involve placing the thermometer in the mouth, the rectum, the axilla, or the groin. It does not seem to be sufficiently realized that considerable differences in the temperature recorded in these four situations may be encountered, and the readings are by no means comparable. For example, in a letter following an article by Green and Penfold (1947) on clinical thermometers as a possible source of cross-infection in hospital, Albury (1947) concludes that the best plan would be to take temperatures in the axilla rather than in the mouth, as if readings in these two situations were the same. Fig. 1 from the series to be here reported shows a definite pyrexia for mouth readings which would have largely been missed over a period of ten days if the axillary temperature had been accepted against the usual "normal" as shown on a standard temperature chart. Fig. 2 shows a comparison between rectal and axillary readings which equally in the earlier part, demonstrates a pyrexia by rectal readings which the axillary readings fail to record.

#### Present Investigation

The investigation consisted of observations on 32 children taken at random in a general medical ward unit. The readings were taken at 6 a.m. and 6 p.m. over a period of six

consecutive days giving twelve readings in each child from which the differences were calculated. A standard 'half-minute' thermometer was used and, unless otherwise stated, was left in the chosen site for three minutes before the

Fig. 1—Chart of child aged 9 years, in bed with purpura. Upper line=mouth temperature, lower line=axillary temperature.

Fig. 2—Chart of child aged 15 months in bed with thrombocytopenic purpura. Upper line=rectal temperature, lower line=axillary temperature.

temperature was recorded. When two sites are mentioned two thermometers were used simultaneously. The following results were obtained (all figures are the mean of twelve readings).

- A. Comparison of groin and rectum  
1 Age 1 month rectal reading 1.05° F (0.58° C) higher than groin  
2 2 months 0.92° F (0.51° C)  
3 2 years 1.16° F (0.64° C)  
4 2 1.18° F (0.65° C)
- B. Comparison of groin and mouth  
1 Age 9 years mouth reading 0.76° F (0.43° C) higher than groin  
2 7 0.3° F (0.16° C)
- C. Comparison of groin and axilla  
1 Age 4 years groin reading 0.4° F (0.22° C) higher than axilla  
2 9 0.7° F (0.39° C)  
3 4 months 0.4° F (0.22° C)  
4 14 axilla 0.16° F (0.089° C) groin
- D. Comparison of mouth and rectum  
1 Age 10 years rectal reading 0.16° F (0.089° C) higher than mouth  
2 10 0.35° F (0.194° C)  
3 5 0.15° F (0.083° C)  
4 5 0.3° F (0.16° C)
- E. Comparison of mouth and axilla  
1 Age 8 years mouth reading 1.38° F (0.76° C) higher than axilla  
2 9 0.88° F (0.49° C)  
3 5 0.9° F (0.5° C)
- Comparison of rectum and axilla  
1 Age 9 months rectal reading 1.08° F (0.6° C) higher than axilla  
2 15 1.6° F (0.9° C)  
3 4 years 1.1° F (0.61° C)
- Case 1 was running a high swinging temperature whereas in Cases 2 and 3 the temperatures were between 97° and 100° F.

In the next two groups the temperatures were recorded (with "half-minute" thermometers) after two minutes and after five minutes.

- G. Axilla  
1 Age 6 weeks 5 min. reading 0.75° F (0.42° C) higher than 2 min. reading  
2 9 years 0.96° F (0.53° C)  
3 5 0.9° F (0.5° C)  
4 6 0.45° F (0.25° C)  
5 10 0.4° F (0.22° C)
- H. Groin  
1 Age 2 months 5 min. reading 0.85° F (0.47° C) higher than 2 min. reading  
2 2 years 1.4° F (0.78° C)  
3 6 0.4° F (0.22° C)  
4 4 0.6° F (0.33° C)  
5 1 week 0.5° F (0.27° C)
- Case 2 in this series was that of an abnormally obese child.

Certain other observations were made which serve to confirm what others have recorded, and it would be tedious to give details. For example, the child who is in bed shows a closer correlation between readings in groin and rectum than the child who is up and about the ward. The notorious

"normal" temperature recorded in the out-patient department (usually axillary recording) which became "febrile" when the child was warmed up in bed was seen so often as to be regarded as a routine phenomenon—dangerous as it may be

Too much must not be deduced from the small number of children observed, but from nearly four hundred recorded temperatures it is justifiable to conclude (1) that the highest temperature recorded is in the rectum, which is approximately  $1^{\circ}\text{F}$  ( $0.55^{\circ}\text{C}$ ) higher than in the groin,  $0.2^{\circ}\text{F}$  ( $0.11^{\circ}\text{C}$ ) higher than in the mouth, and  $1.3^{\circ}\text{F}$  ( $0.72^{\circ}\text{C}$ ) higher than in the axilla, (2) that the lowest recording is that in the axilla, which is approximately  $0.4^{\circ}\text{F}$  ( $0.22^{\circ}\text{C}$ ) lower than in the groin and considerably lower than in the mouth and rectum, (3) that the average ("half-minute") clinical thermometer does not attain a maximum reading until at least five minutes when the skin temperature is being recorded in the axilla and in the groin

No doubt some of these discrepancies could have been avoided with more accurate thermometers and perhaps with more expert observers, but they represent the ordinary everyday methods employed in a hospital ward with ordinary instruments and the observations of competent nurses in training, supervised for the purpose of this investigation by the senior nursing staff

### Discussion

It may be argued that the slight differences discovered are of little significance. It is true that with a case of pneumonia it does not matter greatly whether the temperature recorded is  $104^{\circ}\text{F}$  ( $40^{\circ}\text{C}$ ) rectal or  $102^{\circ}\text{F}$  ( $38.9^{\circ}\text{C}$ ) axillary. But in cases of rheumatic carditis, for example, or primary tuberculosis, a temperature curve never rising above the "normal" marked on the chart as recorded in the axilla or groin may quite mask a low-grade pyrexia revealed by recordings in the mouth or rectum

These facts have long been known even if in clinical work they are sometimes forgotten. Wright (1945) may be taken as typical of standard teaching. He quotes the normal temperature range (presumably in adults) as  $96.7\text{--}99^{\circ}\text{F}$  ( $36.5\text{--}37.2^{\circ}\text{C}$ ) in the mouth and  $97.2\text{--}99.5^{\circ}\text{F}$  ( $36.2\text{--}37.5^{\circ}\text{C}$ ) in the rectum. He states that the rectal temperature is the highest of the various routes—averaging  $0.5^{\circ}\text{F}$  to  $0.75^{\circ}\text{F}$  ( $0.267\text{--}0.42^{\circ}\text{C}$ ) higher than the mouth. In warm surroundings (i.e., in bed) he thinks the buccal temperature about equals the rectal. Temperature-recording in the axilla or groin he condemns as "inaccurate in thin subjects" (but note the fat child mentioned above) "and otherwise approximates to buccal". For the purpose of clinical paediatrics children may generally be regarded as "thin subjects," and this condemnation may be viewed in glaring contrast to the usual standing orders to nursing staff in children's hospitals to use the axillary or groin situations. Inquiries made during the present investigation suggest that not all children's physicians are aware of the methods of temperature recording used for patients under their care. It would appear that the rectal site is best for babies under 1 year and presents little difficulty. For children over 5 years and certainly over 8 the mouth can be used, especially if the tougher type of "rectal" thermometer is employed to avoid the small danger of breakage. Between these ages, in the toddler, the choice is not so easy.

Psychological objections to the rectal site have been urged, but the evidence seems more theoretical than practical. It may be stated in reply that the rectal route at all ages is widely, if not exclusively, used on the continent of Europe, and the incidence of grave psychological trauma has not been seriously advanced for this large section of the world's population. Secondly, as with so many procedures in chil-

dren, it all depends on the attitude of the nurse dealing with the child. If this is "matter-of-fact" and kindly, and if children are aware of others undergoing the same investigation, it is extremely doubtful if harm is done by the insertion of a thermometer into the rectum. The time factor may be a more serious consideration, for it is generally conceded that the nurse should stand by the child during the rectal reading, whereas skin-recording, and even mouth-recording in older children, can be done for a group at once. What is needed is an instrument which not only claims to be a "half-minute" thermometer but actually records its maximum during this period.

The question of infection is obviously of great theoretical importance, as Green and Penfold (1947) have indicated, an especially when the mouth or rectum is used. The only solution is to have a separate thermometer for each child, kept permanently in a suitable disinfectant between readings. This is, in fact, the practice at many children's hospitals.

For accurate readings the rectal site should be chosen for all children under 5 years and the mouth after this age in most cases. Axillary and groin readings should be given up as inaccurate. Temperature charts should always record which situation has been used.

### Summary

Simultaneous temperature recordings in various situations—mouth, rectum, groin, and axilla—in an unselected series of 32 children show differences of some practical importance. It is argued that the axilla and groin should be discarded as sites for temperature readings. Possible difficulties from the point of view of psychological trauma and infection are discussed.

Thanks are due to the nursing staff of the Hospital for Sick Children, Great Ormond Street, for their careful collaboration.

## INFANTILE DIARRHOEA AND VOMITING

### A REVIEW OF 456 INFANTS TREATED IN A HOSPITAL UNIT FOR ENTERITIS

BY

M. B. ALEXANDER, M.R.C.S.

Assistant Medical Officer North-Eastern Hospital London

Units for the treatment of enteritis of infants were established at most of the infectious diseases hospitals administered by the London County Council. The unit at the North-Eastern Hospital came under my care in January, 1945. The cases recorded in this paper were admitted during the years 1945 and 1946. Early in 1947 the unit was moved to more suitable accommodation in single-cell wards. The experience of that year is not comparable with that of previous years and has therefore been excluded.

The object of this paper is to describe the organization and working of the unit, to discuss the type of case treated, and to analyse the results of treatment.

### Organization

**Accommodation and Equipment.**—Throughout the period 1945–6 the unit was contained in two wards of the composite, or Hoorns, type (Harriss and Mitman, 1947). Each ward was designed to provide accommodation for 31 patients, distributed as follows: 5 in single cells, 6 in double cells, and 20 in groups of 4 in the five bays of the

in in ward. In practice it was found desirable to limit the number of cots in the main ward to 12, with a maximum of 14. The total number of patients in each ward therefore did not exceed 25. Each ward was fully equipped for barrier-nursing. Each bay of the main ward and each cell contained a fixed hand basin with elbow taps. Two steam sterilizers were available—one for instruments and one for crockery. The ward kitchen contained a refrigerator. In addition each ward was equipped with the instruments and apparatus required for intravenous therapy in infants. A set of sterilized instruments and other necessary apparatus were kept on a trolley, ready for immediate use in urgent cases. Sterile fluids for intravenous administration were supplied from a central laboratory in 500-ml bottles with screw caps.

**Staff.**—Both wards were under the direction of the same resident medical officer throughout the two-year period. Off-duty and holiday relief was provided by resident medical officers who had become familiar with the established routine. Uniformity of treatment was thus maintained. Routine medical ward rounds were made three times a day, and the medical officer was available at any time. Each ward was in the charge of a sister who had had general hospital and fever hospital training. So far as was possible, transfers of ward sisters were avoided. The nursing staff comprised fever-trained nurses, general-trained and probationer nurses in training for fever certificates, assistant nurses and ward orderlies. Frequent changes of nursing staff were unavoidable. The number of nurses allocated to the wards varied widely. At first 11 staff by day and 4 by night were available for each ward of 23 to 25 patients allowing a ratio of one nurse on duty to every six infants. As the shortage of nurses became more acute the total allocation for each ward (including sister, nurses, and ward orderlies) was reduced to 6 or 7 by day and 2 by night. Consequently, there were generally three, and often only two, nurses on duty in the ward at any one period of the 24 hours. All nurses were familiar with the technique of barrier-nursing and the general management of infants. In the unit they were taught the indications for the institution and termination of intravenous therapy and the methods of maintaining intravenous drip infusions in small infants.

**General Management.**—Few breast-fed infants were admitted with enteritis. The mothers of these were accommodated with their infants in the cells off the main ward. Maintenance or re-establishment of breast-feeding was usually all that was required for their recovery. The majority of infants with enteritis, and almost all the severe cases, had been artificially fed before admission. For these, feeds were prepared in the kitchen of each ward. All dried-milk feeds were freshly made up as required. Benger's modified milk was prepared twice a day and stored in the refrigerator in the ward kitchen. Hartmann's Ringer-lactate solution (*Extra Pharmacopoeia* 22nd edition 1941) was available, sterilized, in 500-ml bottles.

**Prevention of Cross-infection.**—The cots were widely spaced in the bays of the main ward, and bed isolation and barrier-nursing techniques were employed throughout the unit. Infants with parenteral infections associated with diarrhoea and vomiting were, so far as was possible, nursed in complete isolation in the cells off the main ward. The system of "clean" and "dirty" nurses could not always be employed owing to the shortage of staff. Napkin-changing rounds were made two-hourly, and were so arranged as to be completed before the times of feeds. Individual rectal thermometers were supplied for each infant. Separate gowns were worn when attending to each baby. Soiled linen and napkins were placed in closed bins containing "white disinfectant fluid" and sent to the

laundry twice daily. No sluicing of nappies or other articles was permitted in the wards. Feeding bottles, teats and valves, measuring-jugs and other articles required for preparing feeds were sterilized after each feed and stored in covered containers.

**Laboratory Investigations.**—The routine investigations were cultures of faeces and rectal swabs for known pathogens, red blood cell counts, and haemoglobin estimations. White cell counts were made in all cases at first, but were found of limited value and were later confined to selected cases. Other laboratory investigations were made, as required, but biochemical investigations other than total serum-protein estimations were not made. Specimens of fluids for intravenous administration were taken at the beginning and the end of all intravenous infusions and cultured for contaminating organisms.

### Treatment

The methods of treatment were based on previously reported experience (Alexander and Eiser, 1944). The underlying principles are of sufficient importance in practice to merit restatement.

1. Careful assessment of the infant's condition on and after admission, with particular reference to (a) clinical evidence of dehydration, (b) its degree and duration, (c) the presence of parenteral infection.

2. (a) Prevention of dehydration by ensuring a sufficient fluid intake, or (b) its prompt correction by the administration of adequate fluids by the appropriate route.

3. A short initial period of starvation followed by an early return to milk feeding.

4. Adequate treatment of parenteral infections.

The methods employed were made as simple and as uniform as possible consistent with the varying needs of the individual case. The classification of cases with regard to treatment was into two broad groups—namely, those without clinical evidence of dehydration (non-dehydrates), and those with clinical evidence of dehydration (dehydrates). The dehydrates were further subdivided into two groups: (a) mild or moderate cases which might be expected to respond to oral rehydration, and (b) severe cases for which intravenous therapy was essential. Details of the methods of treatment of artificially fed infants are given below.

### Non-dehydrates

An infant who was not dehydrated on admission was given half-strength Hartmann's solution by mouth two hourly for 18 to 24 hours, in the usual allowance of 24 oz per lb (156 ml per kg) body weight per day. No milk feeds were given during this period and no purgatives were permitted.

After 18 to 24 hours dilute milk feeds were given in the form of one-third-strength Benger's modified milk, 2½ oz per lb per day. If this was well tolerated the feeds were increased to half-strength Benger's the next day, to two-thirds strength on the day following and then to three-quarters-strength. The size of the feeds was increased and the intervals between feeds lengthened after the first or second day.

As soon as the stools became normal the feeds were changed to the milk on which the infant had been fed before admission, beginning with a third-strength dilution of the half-cream mixture and working up gradually by daily increases to the full-strength feeds—half-cream in the case of smaller infants and full-cream for infants over 3 months of age or 10 lb (4.5 kg) in weight. Those of 6 months and over were given a weaning diet. The infant was discharged as soon as he was able to take an adequate diet with no return of diarrhoea or vomiting and was gaining weight.

If at any time the diarrhoea or vomiting recurred the infant was again given half-strength Hartmann's by mouth or 12 hours and then dilute feeds as before. If, however, diarrhoea was excessive or vomiting was persistent, or if the infant refused feeds or became dehydrated, feeds were stopped and intravenous therapy instituted.

#### Dehydrates

An infant who was mildly or moderately dehydrated on admission but who was in good general condition and able to take sufficient fluid by mouth was treated on the same lines as those who were not dehydrated. The usual allowance of fluid was given by mouth, plus 5 to 10 oz (140–280 ml) per day with the object of restoring the fluid deficit. If dehydration was not readily corrected by this means, or if the general condition deteriorated, oral replacement of fluid was abandoned and intravenous therapy begun without delay.

If on admission dehydration was severe or the infant in a collapsed state intravenous therapy was immediately instituted. These infants were given enough fluid intravenously to satisfy their daily requirements, with a supplementary allowance to replace the fluid lost—usually 10 to 20% of body weight in the more severe cases.

The technique of intravenous fluid administration was in accordance with accepted methods (cf Garrod, Batten, and Thursfield, 1947). Strict attention was paid to the prevention of local sepsis and contamination of intravenous fluids. Therapy was begun with 300 ml of half-strength Hartmann's plus 5% glucose given by a slow drip adjusted to deliver the amount required by each infant in the 24 hours. This was followed by 400 ml of human serum or plasma diluted with 150 ml of half-strength Hartmann's. For infants weighing less than 7 lb (3.2 kg) the initial quantities were halved—i.e., 150 ml of half-strength Hartmann's plus 5% glucose, followed by 200 ml of serum diluted with 100 ml of half-strength Hartmann's.

For the first 18 to 24 hours no feeds were given, but the infant was allowed  $\frac{1}{2}$  oz (14 ml) of half-strength Hartmann's two hourly to keep the mouth moist. Small feeds—1 oz (28 ml) of half-strength Hartmann's and then of one-third strength Benger's—were started after this period, the rate of drip being gradually reduced and the amount of feeds slowly increased. The drip was continued, giving alternate Hartmann's and serum, until the infant was fully rehydrated and able to take enough fluid and food by mouth for the daily requirement. If severe diarrhoea, vomiting, or dehydration recurred feeds were stopped and a new intravenous infusion begun. When intravenous therapy was completed the subsequent treatment was as described for non dehydrates.

If signs of anaemia, such as cyanosis or pallor, were present oxygen was administered, using an oxygen tent. Many of the severe cases showed a degree of pallor, and oxygen was freely used on the assumption that this was a sign of incipient circulatory failure. The marked clinical improvement frequently observed would seem to justify this precaution.

Infants with red blood cell counts of less than 2.1 millions or haemoglobin readings below 50% were given whole blood intravenously, but only after haemoconcentration had been corrected.

#### Additional Therapy

If a parenteral infection was found or suspected the infant was treated with one of the sulphonamides. The choice was sulphadiazine given in doses of 0.5 g hourly (3 g per day) for five days to an infant under 2 years of age. Penicillin, when indicated, was given in doses of 20,000 to 40,000 units intramuscularly at four-

hourly intervals for 5 to 7 days. A combination of sulphadiazine and penicillin was thought generally to be more effective than penicillin alone. Sulphadiazine was usually well tolerated and was given orally even to those infants receiving intravenous alimentation. The relatively unabsorbed sulphonamides, such as sulphaguanidine, were not found to be effective in the control of diarrhoea.

The only other drug used was iron, in the form of a ferrous sulphate mixture, for the treatment of some cases of anaemia. Vitamins A, C, and D were given to all infants, and Vitamin K and the B complex when indicated.

### General Analysis of Cases

#### Method of Admission

Administrative procedure had an important bearing on the type of case admitted to an enteritis unit, and must be taken into account before any critical analysis of results is attempted. Admission was arranged centrally by the Public Health Department of the London County Council at the request of medical practitioners. So far as was possible, a patient was sent to the unit nearest to his home, but if no bed was available there he was sent to any unit which had a vacancy. Each unit therefore admitted cases from all parts of the London County Council area.

The criteria for admission accepted by the Public Health Department were: (1) Residence within the County Council area, (2) an age limit of two years, (3) a medical certificate that the case was one of "enteritis" or "gastro-enteritis" and required admission to hospital.

Infants arriving at an infectious diseases hospital in an LCC ambulance and certified as suffering from enteritis had to be admitted. The medical staff could exercise no selection in the matter of admission to the hospital. Admissions therefore included cases of diarrhoea and vomiting of all types and of all degrees of severity. Admission of the case to the enteritis unit, however, was at the discretion of the admitting officer, and infants with diarrhoea incidental to some specific infectious disease could usually be accommodated in other wards of the hospital.

#### Admissions to Enteritis Unit

During the two-year period 1945–6 the number of infants admitted to the enteritis unit of the North-Eastern Hospital was 686, of whom 541 were under the age of 1 year and 145 were between 1 and 2 years of age. These infants came from all parts of the LCC area. Some were admitted from their homes, some from residential nurseries, and some from general hospitals. The numbers of infants in each of these age groups admitted during each year are shown in Table I. In 53 cases no evidence of disease could

TABLE I—All Cases Admitted to Unit 1945–6 Age and Diagnosis

Year	Age in Years	Total Cases Admitted	Diagnosis		
			No Obvious Disease	Diseases Other than Enteritis	Enteritis
1945	0–1	261	8	24	229
	1–2	97	20	36	41
Total		358	28	60	270
1946	0–1	280	20	33	227
	1–2	48	5	19	24
Total		328	25	52	251
Grand total		686	53	112	521

be found, 112 infants had other diseases, including bacillary dysentery (36), other specific infections (17), respiratory infections (39), and miscellaneous illnesses (20). All have been excluded from this series.

During 1946 an effort was made to limit the number of admissions of infants over 1 year of age. Of the 65 infants over 1 year old who had enteritis only two were sufficiently dehydrated to require intravenous therapy and none died. This group will therefore not be considered further in this series. The subsequent analysis deals only with the 456 infants under 1 year of age treated in the unit for diarrhoea and vomiting.

#### Analysis of Enteritis Cases 0-1 year

Table II gives an analysis of these 456 cases showing the number of cases in each 3-months age group, the number of infants who were dehydrated on or after admission, and the number of deaths. Comparison of the dehydration rates with those quoted in previous series (Campbell and Cunningham, 1941, Alexander and Eiser, 1944) shows that

TABLE II—Enteritis Cases under 1 year Dehydration and Mortality

Age Groups	No of Enteritis Cases	Dehydrated on Admission	No Dehydrated after Admission Only	Total Dehydrated on or after Admission	Per cent Dehydrated	No of Deaths	Fatality Rate % All Cases	Fatality Rate % among Dehydrates
I 0-2 months	149	54	27	81	54.4	11	7.4	13.6
II 3-5	171	84	26	110	64.3	6	3.5	5.5
III 6-8	77	41	6	47	61.0	3	3.9	6.4
IV 9-11	59	16	4	20	33.9	2	3.4	10.0
Total	456	195	63	258	56.6	22	4.8	8.5

the cases were as severe as any likely to be encountered in a representative sample of infants with enteritis and comparable with any other such sample.

The majority of the infants (320) were under the age of 6 months on admission, and 17 of the 22 deaths occurred in this group. There were 15 infants under the age of 28 days, and of these two died.

The fatality rates are shown for all cases and for infants who were dehydrated. All the deaths occurred among infants who were dehydrated on or after admission. The usual fall in fatality rate with increasing age is shown, but, owing to the small number of deaths and the small number of cases in age groups III and IV, the differences between age groups do not reach statistical significance in this series.

A total of 258 infants were dehydrated during the course of their illness. Of these, 146 were dehydrated on admission only, 10 (6.8%) of them dying. Forty-nine of the infants dehydrated on admission responded to treatment, but became dehydrated again more than seven days after admission, in this group there were six deaths (12.2%). Sixty-three infants became dehydrated for the first time more than seven days after admission, and of these six died (9.5%). Thus 112 infants relapsed with dehydration, with 12 deaths (10.7%).

TABLE III—Cases of Enteritis Treated during each 6 Months Period of 1945-6 with Dehydration and Fatality Rates

6-Monthly Periods	No of Enteritis Cases	Dehydration		Deaths		
		No	%	No	Fatality Rate % All Cases	Fatality Rate % among Dehydrates
Jan-June '45	106	69	65.1	12	11.3	17.0
Jul-Dec '45	123	62	50.4	3	2.4	4.8
Jan-June '46	85	53	62.4	2	2.4	3.7
Jul-Dec '46	142	74	52.1	5	3.5	6.7
Total 1945-6	456	258	56.6	22	4.8	8.5

Of the 236 infants who were dehydrated and recovered 73 were rehydrated by oral administration of fluid. The remaining 163 required intravenous therapy for correction of their dehydration. In all, 244 separate infusions were given.

Table III shows the number of infants treated in the enteritis unit during each of the four six-months periods of 1945 and 1946, the number who were dehydrated and the number of deaths. The number of admissions and the dehydration rates were fairly constant for each year. There was a sharp fall in the case mortality from 11.3% in the first six-months period to 2.4% in the second period, and this latter rate was maintained for the succeeding two periods. The differences between the first and subsequent periods are statistically significant in each case an exact probability test gives  $P < 0.02$ .

#### Parenteral Infections

Among the 456 infants of this series a parenteral infection was found on admission in 238 cases (52.2%). In a further 46 cases a parenteral infection became apparent for the first time after admission. In the remaining 172 cases, no evidence of parenteral infection was found throughout

TABLE IV—Incidence of Parenteral Infections on Admission and after Admission

Age Groups I-IV	No of Enteritis Cases	Parenteral Infections on Admission		Parenteral Infections on and after Admission	Parenteral Infections after Admission Only	Total Parenteral Infections	
		No	%			No	%
I 0-2 months	149	74	49.7	29	18	92	61.7
II 3-5	171	89	52.0	40	18	107	62.6
III 6-8	77	37	48.0	9	6	43	55.8
IV 9-11	59	38	64.4	3	4	42	71.2
Total	456	238	52.2	81	46	284	62.3

the stay in hospital. Table IV shows the number of infants in each age group who had parenteral infections on or after admission.

The type of parenteral infection found on admission in each age group is given in Table V. It will be seen that

TABLE V—Showing Types of Parenteral Infections Found on Admission in Each Age Group

Parenteral Infections on Admission	II					Total
	0-2 Months	3-5 Months	6-8 Months	9-11 Months		
Upper respiratory infections excluding O.M.	27	18	13	19		77
Suppurative otitis media alone	7	10	2	1		20
Suppurative otitis media + other conditions	4	10	4	6		24
Bronchitis	8	14	6	6		34
Bronchopneumonia	11	23	7	2		43
Skin infections	8	5	2	1		16
Miscellaneous	9	9	3	3		24
Total parenteral infections on admission	74	89	37	38		238
Total cases of enteritis	149	171	77	59		456

the majority were infections of the respiratory tract—the miscellaneous group includes urinary infections, stomatitis, etc.

It is of interest to note that only 44 infants showed evidence of suppurative otitis media on admission. In 32 infants this condition developed during the course of their illness. Thus only 76 of the 456 infants in this series had suppurative otitis media. Nine others had 'red drums' associated with upper respiratory infections—these have been classified under the heading of 'coryza'. In all cases the ears were inspected on admission and when ever a pyrexia or any relapse of the diarrhoea or vomiting occurred. Myringotomies were performed in 49 cases. Mastoidectomy was carried out in only four cases. Post-mortem examinations were made of all but five of the 22 infants who died, and in only one case was pus found in the middle ears at necropsy.

Table VI is an analysis of the association of dehydration with parenteral infection found on admission. Of the total of 456 infants, 238 (52.2%) showed evidence of parenteral infection on admission, and in 218 (47.8%) no parenteral

TABLE VI—*Relationship of Parenteral Infection to Dehydration on Admission*

Dehydration on Admission	Parenteral Infection + on Admission		No Parenteral* Infection on Admission		Total
	No	%	No	%	
Dehydration + Not dehydrated	112 126	57.4 48.3	83 135	42.6 51.7	195 261
All cases	238	52.2	218	47.8	456

$\chi^2 = 3.75$   $P = 0.053$

infection could be found. Among the 195 infants who were dehydrated on admission parenteral infections were found in 112 (57.4%) and were not detected in the remaining 83 (42.6%). A  $\chi^2$  test on this Table gives only weak support to any suggestion of association between dehydration and parenteral infection.

#### Analysis of Deaths

There were 22 deaths in this series. Three infants had overwhelming parenteral infections associated with severe dehydration which failed to respond to intensive treatment. Four infants died of severe parenteral infections which, in retrospect, must be regarded as having been inadequately treated. In one of these the institution of intravenous therapy also appears to have been delayed. In one case bronchopneumonia and an empyema were not discovered until necropsy. No sulphonamides had been administered.

Four cases were moribund on admission. One of these had already been given abundant subcutaneous saline infusions, and was waterlogged and oedematous on arrival. Another of these infants was extremely dehydrated and collapsed. Intravenous therapy was attempted but was unsuccessful, and the child died 15 hours later. Two infants were severely dehydrated on admission, failed to respond to adequate intravenous therapy, and died in five and eight days, respectively. It is thought that in these two cases the dehydration was irreversible.

Two infants, and probably a third, were given amounts of fluid intravenously which proved to be excessive and died of cardiac failure. In one case the routine red blood cell count was inadvertently omitted and a severe anaemia—RBC 1,910,000—was not discovered until the day of death. This infant had a severe bronchopneumonia which failed to respond to chemotherapy. It is possible that she would have recovered with the aid of a blood transfusion.

The four remaining cases failed to respond to apparently adequate treatment of their dehydration.

#### Discussion

The cases described in this series may be considered a representative sample of infants admitted to an enteritis unit in the London County Council area. They were of average severity, and the clinical findings and results of treatment should therefore be generally applicable to infants admitted to hospital with enteritis.

No discussion of the aetiology of infantile diarrhoea and vomiting will be attempted here. It is of interest, however, that the findings in this series are not in accord with the view that parenteral infections are the main causative factor in the onset of diarrhoea and vomiting. From Table VI it may be seen that in a high proportion of the more severe cases of enteritis parenteral infections were not detected although carefully sought.

Neither can otitis media be implicated as a major factor in the onset or relapse of diarrhoea and vomiting in this series, since it was found in only 76 of the 456 infants. It seems probable that the smallness of the number of mastoidectomies required was due to the more effective methods available for the treatment of suppurative otitis media and to the earlier correction of dehydration.

Parenteral infections, however, when present, may adversely affect the infant's response to treatment of the diarrhoea and vomiting especially when associated with dehydration. It is essential, therefore, that these should be carefully sought for in all cases and energetically treated. Failure of dehydration to respond to adequate intravenous therapy should suggest the possibility of an associated parenteral infection. In such cases if there is continued pyrexia with no improvement in the general condition it has become the custom in this unit to give the infant a full course of sulphadiazine even though no definite parenteral infection has been found. It is considered that this practice is amply justified by cases such as those described in the analysis of deaths.

Dehydration remains the chief cause of the continued high fatality rate of infantile diarrhoea and vomiting and its prevention or early correction constitutes the most important factor influencing recovery. In this series there were no deaths among the 198 infants who were not dehydrated. Among the 258 infants who were dehydrated there were 22 deaths. With earlier recognition and correction of dehydration nearly half of these deaths might have been prevented.

The ability of the infant to conserve water is relatively less than that of the adult. Therefore in any condition characterized by continued fluid loss dehydration occurs more readily in infants and reaches an irreversible stage more rapidly (Gimble 1947). The condition which most commonly produces dehydration in infants is diarrhoea and vomiting. It should be remembered that this condition also leads to starvation. Therefore an infant who has become dehydrated is in need of food as well as of water and electrolytes. If these cannot be supplied by the oral route parenteral alimentation becomes essential.

Feeding by the gastric drip method does not permit of complete alimentary rest for the infant with severe diarrhoea and vomiting. Diarrhoea usually continues, absorption is uncertain and dehydration and starvation are prolonged. This method was tried in a series of 22 dehydrated infants, and dehydration was corrected in only two cases. The remaining 20 infants became more severely dehydrated and required prolonged intravenous therapy. The gastric drip method was therefore abandoned.

Water and electrolytes may be administered by the subcutaneous or intraperitoneal routes but in all but the mildest degrees of dehydration absorption is unreliable. Neither is it possible to provide the infant with adequate amounts of food by these routes. The intravenous route is the only reliable way of supplying such an infant with water and electrolytes, and food in the form of glucose and serum or plasma.

Early institution of intravenous therapy is essential for infants with diarrhoea and vomiting who are severely dehydrated. By this means complete alimentary rest is assured, dehydration is corrected promptly, and starvation is prevented. It is the practice in this unit to continue intravenous alimentation until diarrhoea has ceased or greatly decreased, dehydration is fully corrected, and the infant able to take sufficient fluid and food by mouth for daily maintenance. If watery diarrhoea or dehydration recur, oral feeding is stopped and intravenous therapy reinstituted.

Approximately 40% of the infants admitted to the unit required intravenous therapy. This could have been administered only in a hospital with the necessary facilities. The success of treatment is therefore dependent on (1) recognition of dehydration in its early stages and admission to hospital of all but the mildly dehydrated, (2) correct assessment of the degree of dehydration in relation to the requirements of treatment, (3) a team of trained and experienced staff to carry out the necessary treatment. These requirements are best fulfilled by the establishment of self-contained hospital units for the treatment of enteritis.

The recognition of dehydration in its early stages is within the province of all medical practitioners, and the need for early treatment should be more widely appreciated. The assessment of the degree of dehydration and the treatment required in each case is essentially dependent on clinical judgment gained through practical experience. The successful application of these methods of treatment depends upon the training of the medical and nursing staff of the unit.

The figures shown in Table III lend support to this view. The fall in fatality rates after the first six months of 1945 appears to be directly related to the training of the nursing staff, since the technique of treatment was the same throughout the two years and the degree of severity of the cases did not vary from one year to the next. The distribution in age groups did not vary significantly in successive periods, nor during the first six-months period was there any preponderance of the younger age groups, in which a higher fatality rate might be expected. Owing to necessarily frequent changes of staff, in approximately six months most of the nurses in the hospital had worked in the enteritis unit and had become familiar with the routine management and treatment established there. Thereafter, although shortage of staff became a serious problem, all the available nurses were acquainted with the nursing and treatment of the dehydrated infant and were able to maintain the high standard of care necessary for these babies.

In this series 112 infants relapsed with dehydration. Since the nature of the infecting organism or organisms in diarrhoea and vomiting is not yet known, it is not possible to say what proportion of these relapses was due to cross-infection or to re-infection. The possibility of such an occurrence, especially in an open ward, must, however, be borne in mind. The observations in a previous series (Alexander and Eiser, 1944) are of interest in this connection. In that series the infants were nursed in two different wards—an "open" barrier ward and a single-cell barrier ward. The technique of nursing and treatment were identical, and the numbers of admissions and dehydration rates on admission were the same for both wards. Yet the relapse rate in the open barrier ward was four times as great as that in the single-cell ward.

It seems advisable, therefore, that bed-isolation and barrier nursing should be rigidly enforced in enteritis units, which should whenever possible, be accommodated in wards of single rooms or cells. By the establishment of such units, staffed by trained medical officers and nurses, much may be done to reduce the number of infants still dying of diarrhoea and vomiting.

### Summary

The organization of a hospital unit for enteritis of infants is described and the treatment is outlined.

The results of treatment for the years 1945 and 1946 are detailed. 456 infants under the age of 1 year were treated in the unit during this period. 258 (56.6%) of these infants were dehydrated during the course of their illness. There were 22 deaths, giving a case mortality of 4.8% for all cases, or 8.5%

for infants who were dehydrated. There were no deaths among infants who were not dehydrated. Parenteral infections were found on admission in 238 cases (52.2%).

The association between parenteral infections and dehydration is low, and this series does not support the view that parenteral infections are a major factor in the causation of diarrhoea and vomiting. The need for careful search for parenteral infections is however stressed from the point of view of treatment.

The importance of prevention or early correction of dehydration, the necessity for intravenous therapy in severe cases, and the need for prevention of cross infection are emphasized. This implies the provision of adequate facilities and a staff of medical officers and nurses experienced in the technique of barrier nursing and the treatment of dehydration in infants.

It is suggested that these requirements are best fulfilled by the establishment of self contained hospital units for the treatment of enteritis.

My acknowledgments are due to Dr E H R Harnes (late medical superintendent of the North Eastern Hospital) and to Dr Robert Swyer, acting physician superintendent, for facilities to carry out this work. I am greatly indebted to the resident medical officers and to the nursing staff for their enthusiastic co-operation and to Mr L G C Maslen for all laboratory work. I wish to thank Mr B Benjamin, statistician to the LCC Public Health Department for help with the statistical analyses.

## MULTIPLE MYELOMA TREATED WITH STILBAMIDINE AND PENTAMIDINE

BY

ANGUS E BREWER, MRCS, LRCP  
*Clinical Pathologist Hampstead General Hospital*

Von Rustizky (1873) was the first to describe the disease of multiple myeloma, the name of plasma-cell myeloma being proposed 27 years later by J H Wright (1900). Macintyre (1850) had already described a case of multiple bone tumour, calling it mollities ossium, which had a peculiar "animal matter" in the urine that became evident on gentle heating and disappeared on further heating. He sent the urine to Bence-Jones (1848) for examination, and the substance subsequently became known as Bence-Jones protein. About the same time Dalrymple (1846) gave a clear description of the bony changes in a case he reported on as mollities ossium.

Life insurance tables give the incidence of multiple myeloma as 0.03% of all malignant growths or 3% of all bone sarcomas, but recent collections of cases published suggest that the figures may be higher. Thus Batts (1939) found 40 cases in 200 primary malignant tumours of bone, and Bayrd and Heck (1947) saw 18 in a period of six months. Improved methods of pathological investigation and the attention drawn to the disease by publications have no doubt been largely responsible for the increased number of cases diagnosed.

Multiple myelomatosis is usually described as a fatal disease of middle life, occurring twice as often in males as in females and characterized by multiple tumours growing from the marrow and eroding the bone in a characteristic

## Case 4

A well built woman aged 42 consulted her doctor for an aching pain in the middle and lower parts of the back. It had been present for some months. She had recently noticed some breathlessness on exertion and an increasing weakness. Physical examination did not reveal any cause for these symptoms.

The blood count disclosed a macrocytic anaemia (Hb 41%) and a leucopenia (3800 per cmm) due to a reduction in neutrophils the latter showing a marked shift. There were 3% of myeloma cells in the blood smears which were particularly grey. At the same time a routine radiograph of the chest showed an expanding and bone destroying tumour of the seventh rib posteriorly. Radiographs of the rest of the skeleton did not reveal any other lesions. A sternal puncture showed 61.5% myeloma cells with the red cell series (3%) and the neutrophil series (20%) greatly reduced, findings which indicated extensive and widespread involvement of the marrow in spite of the fact that only one small tumour was apparent on the x-ray film. The serum globulin (5.6 g) and alkaline phosphatase (26 units) were considerably raised. The urine was normal.

After a transfusion a course of deep x-ray therapy was given without any improvement and the pain became worse. A total of 4 g of stilbamidine was then given over a period of two months; this resulted in complete alleviation of pain, although the general condition continued to deteriorate and the urine now contained protein and casts. Bence-Jones protein was never found. Over the next two months 3.8 g of pentamidine was given, but the patient went steadily downhill and died from complete aplasia of the marrow due to replacement by myeloma tissue and renal failure. There were generalized haemorrhages and purpura.

## Case 5

A stocky well-built Greek complained in January 1946 of intermittent epigastric and subcostal pain. He was investigated for peptic ulcer in hospital but no definite diagnosis was made. Over the next year the pain became much worse, was more extensive and continuous, and was accompanied by increasing weakness.

In June 1947 the blood count showed an extensive leuco-erythroblastic anaemia (Hb 36%) with 3% myeloma cells in the differential count. A sternal puncture revealed 86% myeloma cells with very scanty red cell series (less than 1%) and white cell series (13%). The serum globulin was raised (3.7 g). The urine contained albumin casts, and pus although Bence-Jones protein did not appear until the very terminal stages.

A radiograph of the skeleton taken in June 1947 showed advanced generalized myelomatosis with considerable collapse of the spine and many fractures. Support was given by a spinal jacket and he received a course of x-ray therapy without any improvement or relief of pain.

Stilbamidine therapy was started on Oct. 11 and totalled 8.6 g over a period of three months combined with transfusions of folic acid and iron and penicillin for broncho-pneumonia. Apart from improvement in the pain the patient gradually became worse and died on Jan. 12, 1948. During the last two weeks 2.1 g of pentamidine was given also without improvement.

Necropsy revealed the ribs, sternum and vertebrae to be almost entirely replaced by myelomatous tissue. In the long bones the marrow cavities were enlarged and filled with such tissue. There were very numerous pathological fractures. Sections and smears showed masses of myeloma cells about 7 $\mu$ , containing inclusion bodies (see below). Both kidneys showed pyelonephritis. Sections of the kidneys and the liver revealed myelomatous infiltration.

## Case 6

A large well built man aged 63 was admitted with generalized purpura, haematuria, epistaxis, melena and a right testicular haemiorchoma. Generalized aching pains had been present for the last few months, had become worse in the last few weeks and were now accompanied by some loss of feeling in the

hands and feet. Marked arteriosclerosis and some chronic bronchitis were present. The central nervous system apart from rather weak jerks, showed no abnormality.

Blood examination showed a normal red cell count and thrombocytopenia, a leucocyte count of 10,000 per cmm with a marked neutrophil shift and an eosinophilia (23%) and the presence of scanty myeloma cells. A sternal puncture revealed 9% myeloma cells with 4% plasma cells. The red cell series (14%) and the neutrophil series (31%) were reduced, eosinophils (18%) were increased. The serum globulin (7.8 g) was greatly raised. The serum calcium (11.8 mg) and plasma alkaline phosphatase (169 units) were slightly increased. The urine contained protein with some granular casts but no Bence-Jones protein. A radiograph of the skeleton failed to show any abnormalities. A total of 4.2 g of stilbamidine was given over two months. Clinical improvement was at first limited to disappearance of the purpura but on completion of the treatment the patient could get about fairly well and said that his pains were not as bad.

## Effects of Treatment

*Clinical*—Case 3 has shown definite improvement with relief of pain and could get about for short distances twelve months after the diagnosis was made and approximately two years from the time of the first symptom. Case 6 has shown some improvement and is fairly mobile six months after the diagnosis and twelve months from the time of the first symptom. In Cases 4 and 5 the patients, who had very extensive marrow involvement before treatment, died after a period of some months without showing any improvement except for the relief of pain. In Cases 1 and 2 the patients died suddenly after a few injections of stilbamidine, the first from renal failure and the second from agranulocytosis.

*On Myeloma Cells*—Snapper and his colleagues demonstrated the development of basophilic inclusion bodies in the cytoplasm of myeloma cells in patients receiving stilbamidine. These bodies appeared to be compounds of stilbamidine and ribose nucleic acid. It is suggested that the ribose nucleic acid becomes dissociated from its protein in the ribose nucleic complex and attached to the stilbamidine to form a substance which appears within the cytoplasm of the cell as deeply basophilic granules. These granules ultimately coalesce to form inclusion bodies. Such inclusion bodies were demonstrated in Cases 3, 4, and 6 (Figs 1 and 3). Case 5 never developed them in spite of the

FIG. 1—Two typical myeloma cells, one containing at least 12 well-formed inclusion bodies and the other three earlier and less distinct bodies. ( $\times 850$ )

large dosage and the length of treatment. Cases 1 and 2 ended fatally before there was time for them to develop. A reduction in the number of myeloma cells was obtained by sternal puncture in Case 3 (15% to 3%) and in Case 6 (9% to 5.5%) (Table I). In both cases the small number of myeloma cells originally present in the peripheral blood disappeared.

*Biochemical*—No improvements were obtained except in Cases 3 and 6 (Table II). In Case 3 the plasma globulin, the alkaline phosphatase, and the serum calcium returned to normal. In Case 6 they showed a fall towards normal.

*Haematological*—Cases 3, 4, and 6 developed a very considerable eosinophilia in the early stages of treatment (74% in Case 6). In Case 4 this persisted until death but in

impression of a dispersing nucleolus. The cytoplasm stained irregularly, giving a foamy appearance. As a rule deeply basophilic it had a definite and distinctive purplish tint (Jenner-Giemsa stain), often contained a number of azure granules, and was sometimes vacuolated.

The primitive or blast type (Fig 5) was about  $26\ \mu$  in diameter. A definite nuclear membrane enclosed a nucleus which occupied three-quarters of the cell space and possessed one large nucleolus with sometimes up to three small nucleoli in addition. The chromatin assumed a definite

FIG 2—Early stage in development of typical myeloma cell: disappearance of nucleoli and condensation of nuclear chromatin. Outline of the foamy cytoplasm distorted by spreading ( $\times 965$ )

FIG 3—Typical myeloma cell containing stilbamidine inclusion bodies. Pale central nuclear zone surrounded by coarse chromatin masses ( $\times 965$ )

FIG 4—Multinucleated myeloma cell ( $\times 965$ )

FIG 5—Blast type of myeloma cell containing three nucleoli ( $\times 850$ )

stippled pattern. The cytoplasm presented the same features as described in the typical myeloma cell but did not contain granules or vacuoles nor stain so deeply.

The multinuclear cells usually contained two nuclei but occasionally had four or more, and varied in size from  $20$  to  $40\ \mu$ . The nuclear and cytoplasmic characteristics were identical with those described in the typical myeloma cell.

In all cases the myelogram showed an increase in the number of normal plasma cells—i.e., plasma cells indistinguishable morphologically from those found in normal marrow.

### Comments

The fact that stilbamidine has such a favourable influence on the pain of multiple myeloma constitutes an advance in the treatment of this malignant disease. The method of administration by intramuscular injection is simple and not usually accompanied by severe local or general reactions provided the precautions outlined are taken. In addition stilbamidine seems to have a specific effect upon the protoplasm of some myeloma cells which is evident in fixed stained preparations. While this effect does not bring about complete disappearance of the cells there is evidence that it hinders their increase and dissemination, allowing local healing reactions to take place. The fact that no other cells but myeloma cells are affected suggests that the protoplasm and protein metabolism of the latter differs from that of other cells. Snapper (1946a) states quite definitely that stilbamidine has no effect in other malignant diseases such as leukaemias and Hodgkin's disease.

Two prime factors seem to influence the success of treatment: (1) the initial blood count findings, which are a reflection of the state of the marrow, and (2) the extent of renal involvement.

Those cases which presented with a serious anaemia did not improve. The malignant process was evidently too widespread and had replaced too much normal marrow to permit recovery of haemopoiesis. It seems likely that not enough stilbamidine could be given to have an effect on all the myeloma cells. For example, in Case 5, which received  $8.6\text{ g}$ , inclusion granules were demonstrated in only 7% of the myeloma cells, and this figure did not vary significantly whether the tissue examined was from the ribs, sternum, vertebrae, or femur.

The one patient showing extensive renal involvement (Case 1) died in uraemia after only six injections, suggesting that the stilbamidine had provoked an unfavourable renal reaction.

Snapper (1946a) stated that stilbamidine gave its best results in patients with widespread but not large osteolytic lesions and with normally functioning kidneys. Detailed information on the blood counts and marrow findings was not given.

### Summary

Reference is made to some of the literature on multiple myeloma, the difficulty of early diagnosis, and the help that pathological investigation may give.

A detailed description is given of six cases and their treatment with stilbamidine by Snapper's method. (Two cases also had pentamidine.) Four of the cases were fatal and two have made some clinical recovery. These results do not compare very favourably with those of Snapper, who reported seven out of fifteen showing continued improvement.

The outstanding clinical feature of treatment with stilbamidine is the relief from pain.

The morphological features of the abnormal cells found in the marrow and the appearance of inclusion bodies in their cytoplasm as the result of treatment are described.

My thanks are due to Dr H. V. Morlock, Dr Harold Davis, Dr Lindsey Batten, Dr K. Blatchley, Dr Gray Thomson, and Dr Z. Leitner for the opportunity of studying these cases; to the laboratory and nursing staffs for their co-operation, and to Mr J. H. Hunter for the photomicrographs.

The Executive Board of WHO has authorized the Director General to sign a preliminary agreement, as soon as 14 of the American Republics have deposited their instruments of ratification of the WHO constitution, between WHO and the Pan American Sanitary Organization providing for the ultimate establishment of that organization as the WHO regional organization for the western hemisphere. The Executive Board has also recommended that WHO establish contacts with the following international non-governmental organizations: International Union against Venereal Diseases, International Union against Tuberculosis, International Union against Cancer, World Federation for Mental Health, International Committee of the Red Cross, International Hospital Federation, International Academy of Forensic and Social Medicine, International Leprosy Association, International Association for the Prevention of Blindness.

## SEPSIS IN RELATION TO TUMOURS

### CLINICAL IMPLICATIONS OF AN EXPERIMENTAL STUDY

BY

P BROWNING, MB, ChB

(From the Departments of Pathology and Bacteriology  
University and Western Infirmary, Glasgow)

The occasional occurrence of sepsis in surgical wounds maintained under rigid aseptic conditions leads to the inference that such infection can take place by routes other than direct contact from without. Learmonth (1924) described invasion of undamaged muscle of an arm by *Clostridium welchii* following a partial gastrectomy. Okell and Elliott (1935) demonstrated the transient presence in the blood of organisms associated with oral sepsis. Buchanan and Kyles (see C H Browning, 1944) by repeated blood cultures showed the occurrence of bacteraemia after minor surgical intervention in a limited area where infection is present, as, for example, in the extraction of teeth. Such circulating organisms are no doubt usually disposed of rapidly by the blood, as indicated by the work of Wright and Douglas (1903), but where persistent bacteraemia exists and there are sites of lowered tissue resistance conditions will be favourable for the establishment of secondary metastatic infection.

Butler and Valentine (1943) stressed the importance of small initial staphylococcal lesions in maintaining bacteraemia—e.g., those occurring under hard skin or beneath a scar. Damage following slight trauma will supply conditions favourable for secondary localization, and degenerating tumour tissue would also appear to afford an excellent nidus in which pyogenic organisms may settle. Muir (1941) has stated that tumours have little resistance to bacterial invasion, and Boyd (1947) emphasized the part played by sepsis as a cause of death in cancer of the human subject.

#### Experimental Investigation

It was therefore decided to ascertain experimentally whether such abnormal tissues are in fact especially apt to harbour pyogenic organisms brought by the blood stream. The problem resolved itself into balancing the factors of tumour growth and progress of infection so that the effects of both might be assessed. A rat sarcoma originally induced by styryl-430 (P Browning, 1941) provided a readily transplantable tumour with a regular progressive course of sufficient duration to permit observation both of the effect of the new growth and of the bacterial agent.

Following a subcutaneous injection of a coarse emulsion of about 0.05 g of tumour tissue in saline death takes place in six to eight weeks from pulmonary metastases, or the animal requires to be chloroformed owing to ulceration over the grafted tumour. The strain of staphylococcus was that used by Browning and Calver (1947), as it responds well to treatment with penicillin. It is noteworthy that rodents are naturally resistant to staphylococcal infection, apparently owing to their plasma being little affected by the coagulase of the organism (Hale and Smith 1945), however, virulence may be enhanced in various ways—e.g., by addition of mucin to the inoculum in order to reduce so far as possible the effects of toxin production *in vitro* the inoculum for a rat of approximately 60 g consisted of 1 ml of a 1 in 20 dilution of an eighteen-hour agar growth injected intraperitoneally.

It was necessary to control the infection by chemotherapy, three or four doses each of 1 000–2 000 units of penicillin being injected subcutaneously in the first twenty-four hours after inoculation. This treatment was the minimum necessary to

effect cure in the majority of inoculated control animals without tumours, 36 out of 43 being cured. Those which did not respond to the therapy died from septicaemia within a few days. In the survivors there were no focal lesions apart from occasional transitory suppuration in the needle-track of inoculation which appeared about a week after infection and which lasted for only a few days. Out of 52 inoculated but untreated animals 43 died within twenty-four hours from staphylococcal septicaemia, within seven days the nine survivors had to be chloroformed owing to extensive sepsis located in the inoculation track.

Tumour-bearing rats were inoculated seven to twelve days after grafting, when the growths were about 1 cm long. Out of 62 which were inoculated and treated with penicillin as above described 52 survived, these were chloroformed before growth of the tumour led to surface ulceration (about five weeks after inoculation). Immediately after death approximately 0.1 g of the tumour was cultured in nutrient broth, several loopfuls of spleen tissue and heart blood were also cultured and other organs examined for lesions, and it was noted that no septic focus existed at the site of inoculation. From the tumours in 19 out of the 52 animals coagulase-positive staphylococci were recovered (often in mixed culture with coliform organisms and diphtheroids). On the other hand, the tumours of all 21 uninoculated tumour-bearing control animals, which had received no penicillin, yielded no staphylococci, although coliform organisms and diphtheroids were often present. Staphylococci were not demonstrated in the spleen or heart blood of either the treated tumour series or the controls. In some of the tumours the staphylococcus was isolated where no gross central degeneration had occurred. These experiments show that localization of pyogenic organisms in a malignant tumour tends to occur as a result of bacteraemia.

#### Conclusions

Two conclusions of clinical importance follow from the results. First, especially in view of Butler and Valentine's work, minor sepsis should be regarded seriously in cancer patients, particularly when radiation therapy may lead to marked lowering of the local resistance. Secondly, since it has been shown that the virulence of pyogenic and other organisms is greatly enhanced by the injection of adrenaline at the site of inoculation (Evans, Miles, and Niven, 1948), where surgery is associated with the use of combined local analgesic and adrenaline the prior clearing up of septic foci which might otherwise seem of little consequence is of prime importance.

I acknowledge with thanks a grant towards the expenses of this work from the British Empire Cancer Campaign.

The American National Multiple Sclerosis Society, which was formed two years ago to stimulate interest and finance research in disseminated sclerosis, has appointed as medical director Dr Cornelius H Traeger. The appointment was made possible by a grant of \$50 000 from the Milbank Memorial Fund. Dr Traeger is a member of the Executive Committee of the New York Rheumatism Association and of the Committee of Research and Education of the American Arthritis and Rheumatism Foundation.

# ANTI-HISTAMINE DRUGS AND RADIATION SICKNESS

BY

W M COURT BROWN, MB, Ch B, B Sc, D MR

AND

R. B HUNTER, MB, MRCP ED

(From the Department of Radiotherapy and the Clinical  
Laboratory, Royal Infirmary, Edinburgh)

Radiation sickness is a syndrome characterized in varying degree by drowsiness, fatigue, nausea, and vomiting. Indirect evidence in favour of the hypothesis that histamine plays a part in the production of this syndrome has been put forward by various workers (Segal, 1939, Leblond and Segal, 1942, Ellinger, 1945, 1946, 1948, Thygesen, 1947). The use of antihistamine drugs in the treatment of radiation sickness has been advocated by Lofstrom and Nurnberger (1946). These authors claimed that the administration of "benadryl" to patients who had developed radiation sickness resulted in a considerable amelioration of symptoms. However, in their paper not enough details were given of the factors governing x-ray dosage and there was no control series of cases. In view of this claim, and also of the possible significance of histamine in the production of radiation sickness, it was considered that a controlled clinical experiment was required to clarify the position.

## Details of the Experiment

The antihistamine used was "anthisan," which has been shown to be the most potent and specific drug available (Schild, 1947, Gaddum, 1948). The patients used for the investigation were those undergoing post-operative irradiation with x rays for carcinoma of the breast. This form of treatment has been standardized in respect of duration of treatment, volume irradiated, and total dosage given (McWhirter, 1948). The 47 patients in this study were divided into three groups, as follows:

**Group A**—Seventeen patients were given anthisan in doses of 0.6–1 g daily. Ten of these received 1 g daily and seven had 0.6 g daily; these latter cases being unable to tolerate the higher dose. The active tablets were administered for five days before starting irradiation so that side effects were minimized and an adequate concentration of anthisan was secured in the tissues.

**Group B**—Fifteen patients were given an inactive preparation identical in appearance to the active preparation. This was also administered for five days before the beginning of irradiation.

**Group C**—Fifteen patients were given no preparation at all.

In every case an assessment of the patient's clinical condition was made by one of us (W M C B) who was entirely ignorant of the type of tablet which the patient was being given. This assessment was made after every fifth treatment in respect of drowsiness, fatigue, headache, nausea, and vomiting. The results are shown in the Table.

Group	Total No. of Cases	No. Developing Radiation Sickness
A	17	16 (94.1%)
B	15	10 (66.6%)
C	15	11 (73.6%)

It will be noted that only a small number of patients have been studied in each group. The investigation had to be abandoned because many of the patients given the active drug became so upset after the starting of irradiation that they would have been unable to continue with x-ray treatment unless the drug had been withdrawn.

**Toxic Effects**—Five out of the 17 cases receiving anthisan developed a toxic erythema accompanied by pronounced constitutional symptoms during irradiation. This patchy erythema, first noted in the posterior shoulder field between the third and fifth days after the beginning of x-ray therapy, spread centrifugally, becoming generalized over the greater part of the trunk and extremities after 48–72 hours. With withdrawal of the antihistamine drug at any stage in its development resulted in a rapid disappearance of the erythema even though x-ray therapy was continued. Such a skin rash never occurs with x-ray therapy alone, and is seen in less than 1% of cases receiving antihistamine drugs for other purposes.

## Discussion

The important practical point that emerges from the study is that in spite of the small number of patients observed it can confidently be stated that anthisan is of no value in the treatment of radiation sickness. Any benefit which results from the administration of other antihistamine drugs is likely to be due to properties other than their antihistamine effect. In addition, not only did anthisan fail to prevent radiation sickness, but, as will be seen from the Table, it appears that those patients receiving the active drug showed a greater incidence of constitutional upset while having x-ray therapy than did either of the two control groups. The difference between Group A and the control series is not statistically significant, but was convincing enough to stop the trial of further cases.

There is considerable evidence to show that histamine may be released in animals in a variety of circumstances. The similarity which exists between the manifestations of certain human states and conditions that can be produced experimentally in animals has led to the belief that histamine plays an important part in certain disease processes. Dale (1948) has suggested that it may possibly have a physiological role in the control of capillary tone. Though there is no direct proof that histamine is released from the tissues by ionizing radiations, the presumption of such a release is an attractive hypothesis which explains many of the manifestations of radiation sickness.

This study seems to show that the administration of anthisan during irradiation with x rays produces a toxic erythema in some cases and may also give rise to a profound constitutional upset. Antihistamine drugs such as anthisan exert their effects by modifying the tissues in such a way that locally released histamine does not produce its pharmacological effects. It is suggested that the local release of histamine resulting from irradiation with x rays and leading to vasodilatation and alteration in capillary permeability may be of physiological importance, and that this type of reaction to injury may well play an important part in preserving the integrity of the organism. The administration of agents such as antihistamine drugs during irradiation may interfere with this protective mechanism, thus accounting for the marked effects noted in this study.

We are indebted to Professors McWhirter, Dunlop and Gaddum for their advice and criticism in the construction of the experiment and during the preparation of the paper. Anthisan tablets and dummy tablets were supplied by Messrs May and Baker, Ltd.

# PATENCY OF VEINS AFTER A NEW TECHNIQUE OF CUTTING-DOWN FOR TRANSFUSION

BY

A J PALMER, MB, BS

AND

A H C WALKER, MRCOG

(From the Departments of Medicine and of Obstetrics and Gynaecology Postgraduate Medical School of London)

During the course of a research project which necessitated the introduction of a catheter into a vein of an arm we felt somewhat guilty, at depriving each patient of a vein which might be required later in an emergency that would conceivably need every available transfusion site. As our patients were all women, and also pregnant, this matter seemed very important. A technique was devised whereby the patency of the vein could be retained for any future occasion. This extremely simple method can be used for any type of transfusion where the introduction of a cannula is necessary. We recommend it particularly to junior house officers, who occasionally waste veins once and for all time. With this method they may still waste a vein through their inexperience, but only temporarily.

## Method

The vein is exposed and mobilized in the usual way, using a small transverse incision, and a loop of fine catgut is drawn underneath by means of an aneurysm needle (Fig 1)

Fig 1

This loop is then cut so that there are two pieces of catgut—the upper piece, A<sub>1</sub> and A<sub>2</sub>, and the lower piece, B<sub>1</sub> and B<sub>2</sub>. The upper piece is not tied, but its two ends are secured with a pair of Spencer Wells forceps. The lower piece is tied once only and the ends secured. A small nick is then made in the vein wall between the two pieces of catgut and the cannula is inserted. It will then be necessary to tie A<sub>1</sub> and A<sub>2</sub> together to secure the cannula, but this step is not necessary in catheter work.

At the end of the transfusion or research catheterization the loop A<sub>1</sub> and A<sub>2</sub> is untied and the free ends are brought through the upper skin edge. Similarly with B<sub>1</sub> and B<sub>2</sub>, the free ends being brought through the lower skin edge (Fig 2)

A<sub>1</sub> is then tied to B<sub>1</sub> and traction applied to the free ends A and B. A few drops of penicillin are applied locally, the cannula withdrawn, and A and B tied together. The wound is then closed, and bleeding from the vein is controlled by direct pressure against the skin. It will be seen that there is no buried catgut, and the loops—A<sub>1</sub> and A<sub>2</sub>, B<sub>1</sub> and B<sub>2</sub>—come out spontaneously after five to seven days.

Fig 2

Few cases of infection occur, and what infection does arise is very mild and is easily treated along usual surgical lines. As a prophylactic measure we recommend the introduction of 200,000 units of penicillin along the catheter as it is withdrawn. The final scar is minute.

A refinement of the technique which makes this operation simpler, affords better control of the vein, and minimizes the chances of infection is to bring the cut ends of each loop out on the skin before nicking the vein wall.

We have been able to show that the veins thereafter remain patent in 100% of cases not only by inserting a needle but also by cutting down on them again in the course of our research.

## Medical Memoranda

### A Note on Direct Inguinal Hernia

Although commonly associated with advancing years, the direct variety of inguinal hernia is not infrequently found in younger men who are not necessarily of poor physique, and it is occasionally seen under the age of 20. For some of the older subjects surgical treatment cannot be entertained, but to others, especially those in active occupations, operation would be more acceptable than a truss if the results were less uncertain. Methods of repair are very diverse, and recurrence rates vary widely between figures of 4.4% (McCloskey and Lehman, 1940) and 35% (Page, 1943).

The narrow strip of conjoint tendon or the free margin of the internal oblique muscle which bounds the broad defect cannot be brought down to the inner end of Poupart's ligament. A Bassini repair is therefore unsuitable and carries an average recurrence rate of 17.6% (Mair, 1945). Instead it is necessary to fill in the intervening gap with fascia or other material which will remain in place permanently. As this gap lies directly underneath the external ring and the weak intercolumnar fascia, it appears advisable also to make full use of the external oblique by displacing the exit of the spermatic cord as far outwards as possible. Subcutaneous transplantation of the cord is not harmful (Rose and Carless, 1940), but doubt has been expressed about the value of the external oblique aponeurosis (Gallie and Le Mesurier, 1924). Yet at operation for recurrent hernia the aponeurosis is found to be an intact sheet, tough and fibrous, the sac emerging from an aperture left for the passage of the cord. Overlapping is less important than closure right down to the pubis.

In Service cases particularly the possibility must be kept in mind that operation may be marred by side-effects, especially upon the locomotor system, for which reason the routine use of fascia cut from the thigh is open to question. As an alternative I sought to apply the older method of McArthur (1901) for the deep half of the repair, to a consecutive unselected series of 55 direct herniae in 38 such patients. Most of them were aged 30 to 40, with extremes of 20 and 45. Five herniae were

of the curious and uncommon funicular type described in Saingot's *Post Graduate Surgery* (1937), the rest diffuse, five were recurrent, of which one was funicular.

Generally the broad based sac was not cut away and the transversalis fascia not considered strong enough to be worth any attention. Disturbance of the internal ring was limited to the removal of seven small oblique sacs. The first couple of turns of the fascial suture picked up the rectus sheath and were drawn fairly taut so as to bring the rectus sheath and Poupart's ligament as close together as possible. This closed the inner part of the defect narrowed the remainder, and left enough of the suture to lace the internal oblique loosely to Poupart's ligament. All areolar tissue under the external oblique and upon the pubis was cleared away and resuture of the aponeurosis started on the pubis. A satisfactory strip could not be obtained from either the upper or the lower leaf of the external oblique in only one instance—a recurrence with an ugly appendicectomy scar close by and much fibrotic matting of the tissues, in this case a Halsted repair was effective.

Results were sought by questionnaire between two and nearly six years after operation (average interval four years). Twenty-nine replies were received relative to 42 fascial repairs, including the four relapsed cases. One-third of the replies were sent by doctors. There were three recurrences. In one, originally bilateral, an associated small oblique sac reappeared on the outer side of the displaced cord. After I excised this the groins withstood without further trouble three years' artillery service followed by eighteen months heavy road work. The only traced simple funicular hernia recurred. A third case was reported to have a definite bulge on the iliac fossa on coughing and an impulse felt through the external ring also. Recurrence was simulated in a fourth case by a venous impulse in the superficially placed cords on coughing but on exploration the repairs proved to be sound. With the possible exception of one patient who was invalided for other causes and later died, all the others have led lives of normal activity, though seven have experienced minor symptoms. Thus, one man has a feeling of weakness on one side, another wears a truss "for extra support," and five have some discomfort at times probably due to intermittent compression of the cord veins in their abnormal course through the musculature.

The series closely resembles that of McCloskey and Lehman's 45 direct herniae with two recurrences, both in results and in details of repair. I have dealt more recently with fifteen more herniae of this kind, including three that were recurrent, at ages ranging from 18 to 54. The same procedure was found to be practicable in all of them, but the later results are not yet known.

It is reasonable to conclude that the method described is very generally applicable to cases of direct inguinal hernia and satisfactory in a fair proportion. Unless the full technique of Gallie and Le Mesurier (1924) is carried out there is not much advantage in using the fascia lata, but a single suture from any source is unlikely to be of much value unless supported by close contact with the overlying aponeurosis.

The production of two new scientific sound films is announced by Crookes Laboratories, London. They are entitled 'Emulsions' and 'The Story of Halibut Oil,' and may be borrowed free of charge by schools, colleges, hospitals, and scientific societies. 'Emulsions,' which runs for fifteen minutes, opens with a series of simple test tube experiments showing the contrast between an emulsion and a suspension. The two types of emulsions and the function of emulsifying agents are then demonstrated. The preparation of emulsions experimentally and industrially by mechanical, chemical, and supersonic means and their uses in daily life are described pictorially. 'The Story of Halibut Oil' is a thirty minute film divided into two parts: the first giving vivid details of life aboard a trawler in Icelandic waters, the second concerned with the scientific treatment of halibut liver, formerly a waste product for the extraction of its vitamin bearing oil. Both films are available in 16-mm and 35-mm sizes and can be supplied at fourteen days' notice.

## Reviews

### ESSENCE OF OBSTETRICS

*Management in Obstetrics* By Andrew M. Claye, M.D. FRCS, FRCOG, Oxford Medical Publications (Pp. 186 illustrated 12s. 6d.) London: Geoffrey Cumberlege (Oxford University Press) 1948.

This is an unusually attractive book on the management of pregnancy and labour both normal and abnormal. The author does not discuss the aetiology and diagnosis of various conditions except when they determine a particular treatment. It is a very practical book, and with a few minor exceptions attributable no doubt to the interval between writing and publication, is thoroughly up to date. There is no room for views other than the author's, and these, clearly based on personal and extensive experience, he presents concisely and dogmatically. In obstetrics there is often more than one good way of doing things so as Professor Claye points out, it is inevitable that not everyone will accept some of the opinions expressed. Practising obstetricians will largely agree with his views, however, and even those who disagree most can hardly fail to respect and enjoy this reasonable and honest account of how to manage the everyday problems of midwifery.

Each of the 36 chapters—essays is perhaps a more fitting term—is on a single subject or form of treatment, none is long and some occupy less than a page. Each, headed by a humorously apt quotation, is a joy in itself, not only for its subject matter but for the style and charm of its presentation. Even the details of antenatal care—which, despite its importance, is one of the most tedious subjects to read about—become interesting when Professor Claye discusses them. The book is not intended to describe the management of all obstetrical conditions, much of its attractiveness would be lost if it did. A notable omission is any account of eclampsia. In general the author has made a happy choice of subjects which cover the essence of modern obstetric practice and that without the 'ifs and buts' which sometimes tend to obscure the picture in the standard textbooks. He is not concerned with the technical details of caesarean section but he is concerned with when and how to carry out episiotomy, how to repair a perineal tear, and how to avoid or treat post partum haemorrhage.

This handy little book (a coat pocket will easily accommodate it, and three or four hours suffice to read it), full of good sense, is evidently intended primarily for the general practitioner obstetrician, but all with a genuine interest in obstetrics, and irrespective of their eminence in this branch of medicine, will find in it a fascination which is the attribute of anything well done.

### FATIGUE

*Fatigue and Impairment in Man* By S. Howard Bartley, Ph.D. and Eloise Chute, M.A. Foreword by A. C. Ivy, Ph.D., M.D. (Pp. 429 \$5.50.) New York and London: McGraw Hill Book Company 1947.

The industrial and social disturbances of the recent years have aroused increasing interest in the practical and academic aspects of 'fatigue'. No excuse need be offered for the publication of any intelligent contribution, nor indeed, since our progress in understanding this problem has been so sluggish, for any novelty of approach. Herein lies the value of this book, whose authors realize that fatigue 'has been used more often as an explanation than as something to be explained' and have made a clear and insistent distinction between fatigue, a subjective phenomenon describable only in personalistic terms and 'impairment' which refers to specific tissue changes identifiable only through physiological and biochemical studies. Fatigue itself they regard 'as an experiential pattern arising in a conflict situation in which the general alignment of the individual may be described as aversion,' and the limpness, tiredness, feeling of inadequacy for further activity, and sense of bodily discomfort, besides being attempts at retreat or escape, are to be recognized as being fatigue and not merely symptoms of it.

In most of the twenty chapters of this book the authors review material selected from sources discussing the psycho-

logical, physiological, and industrial aspects of problems relating directly to fatigue or to certain conditions which are most likely to induce or influence it. Thus we find discussions on various opinions about fatigue, mental fatigue, chronic fatigue, industrial experiences, conflict, and frustration, and on such topics as continuous activity, anoxia, lack of sugar, temperature extremes, salt deficiency, drug actions, sleep, and dietary habits. The authors pay special attention to neuromuscular activity and aspects of visual functioning. Indeed, it was while examining visual activities that S. H. Bartley formulated his concept of fatigue and was led to test it further. His background of specialized training in psychology and biology, and his researches in neurophysiology and vision have influenced its elaboration considerably. He is at present professor of research in the visual sciences at the Dartmouth Eye Institute, and Eloise Chute, a psychologist, is his research associate.

The book is not easily read. Many of its chapters give the impression of a conducted tour of physiology, normal and under certain stresses, with concluding comments that impairment of tissues is obvious but that there is nothing which really relates to fatigue. The main virtue of the book lies in the authors' dogged insistence on the origin and nature of fatigue, which is not to be described, detected, measured, or ascribed to any condition in terms of tissue impairment from which it must be clearly distinguished.

H. M. WHITE

## PARAVERTEBRAL BLOCK

*Paravertebral Block in Diagnosis, Prognosis and Therapy. Minor Sympathetic Surgery.* By Felix Mandl, M.D. F.R.C.S. Translated by Gertrude Kallner, M.D. With foreword by Max Thorek, M.D., F.R.C.S. (Pp. 330, 32s.) London: William Heinemann Medical Books, 1947.

After a short but adequate account of the regional anatomy the author describes fully the various techniques of paravertebral injection. But the book is much more than a mere account of technique. He discusses the application of sympathetic block in many diseases, sets down all the indications for it and with praiseworthy candour mentions those lesions in which this treatment has proved of no avail. To report failures or rather non-successes, is helpful and worthy of being copied. The section on angina is excellent and in the chapters on disorders of the peripheral circulation he finds a place for accounts of many rare and little-known conditions. The book appeals to one as the outcome of much personal experience and wise reading set out with judgment and great interest.

Inevitably the work here and there lags behind modern practice—the printed book cannot keep pace with the research worker in so live a subject. Phenol for example, is mentioned at some length but the author states that it has not been used in practice. There are however to day many patients in whom paravertebral phenol block has been used with complete success, and the question how far this, or a similar method, may replace open operation is part of the research of the immediate future. There is no mention of the use of radio-opaque materials with the injection: the information given by them is often helpful and sometimes chastening. This book is an important contribution to the surgery of the autonomic system. As it contains many facts not easy to come by, it should appeal to all research workers in this field.

E. D. TELFORD

*Diseases of the Chest* (E and S Livingstone, 25s.) by Dr Robert Coepe is already becoming recognized as a classic of its kind and the second edition will be welcomed. For the student there is no better introduction to chest disease and he should not be deterred by its length. The author's style and human approach to his subject make reading easy and enjoyable. But this is not only a book for students: the practitioner will find it a useful guide to treatment and indeed all who are interested in chest disease will read it with pleasure and profit. Most specialists are at times in danger of losing touch with reality and it is refreshing to be brought back to the things that really matter. The clinician says Dr Coepe, "I do as myself by training and tradition to caring for the one who is ill" and this epitomizes the object of his book. In the new edition the author has thoroughly revised the introductory section on anatomy but otherwise there has been little change. The new edition might well include a somewhat fuller account of modern surgery in chest disease.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*L'Infection de Foyer.* By I. Gora. 2nd ed. (Pp. 191, 300 francs.) Paris: Librairie Maloine, 1948.

A monograph on focal infection.

*Klinische Hämatologie.* By Hanns Fleischhacker. (Pp. 624, Sch. 190.) Vienna: Wilhelm Maudrich, 1948.

An illustrated textbook of haematology.

*Les Mathématiques de L'Hérédité.* By G. Malecot. (Pp. 63, 180 francs.) Paris: Masson, 1948.

The mathematics of probability applied to genetic inheritance.

*Therapy Through Interview.* By S. G. Law, M.D. (Pp. 313, 27s.) London: McGraw-Hill, 1948.

An introduction to psychotherapy intended specially for the general practitioner.

*Eclampsie et Eclampsisme.* By H. Vignes. (Pp. 217, 450 francs.) Paris: Masson, 1948.

A study of eclampsia and pre-eclampsia.

*Nursing for the Future.* By E. L. Brown, Ph.D. (Pp. 198, \$2.00.) New York: Russell Sage Foundation, 1948.

A study for the future education of nurses in the U.S.A.

*Pregnancy Diagnosis Tests.* By A. T. Cowie B.Sc., M.R.C.V.S., Ph.D. (Pp. 283, 15s.) Edinburgh: Commonwealth Bureau of Agriculture, 1948.

A review of the literature, particularly with reference to domestic animals.

*La Gelure.* By M. S. Vaghiano. (Pp. 255, 650 francs.) Paris: Masson, 1948.

The symptomatology and treatment of frost-bite.

*Introduction to Diseases of the Chest.* By J. Maxwell, M.D., F.R.C.P. 3rd ed. (Pp. 307, 12s. 6d.) London: Hodder and Stoughton, 1948.

The author emphasizes the necessity for x-ray examination and includes new material on the sulphonamides and antibiotics.

*The Dark Mind.* By R. Goyne. (Pp. 256, 9s. 6d.) London: Stanley Paul, 1948.

A tale of crime and scandal.

*Sex and Citizenship.* By E. F. Griffith, M.R.C.S., L.R.C.P. 4th ed. (Pp. 224, 8s. 6d.) London: Methuen, 1948.

The author discusses the relation between religion and sex and the significance of personal behaviour on the problems of social morality.

*Medical Research in France During the War 1939-45.* By J. Hamburger. (Pp. 306, No price.) Paris: Flammarion, 1948.

Includes papers on the prophylaxis of diphtheria and typhus, anti-histamine substances, intravenous procaine and the treatment of endometriomas with male hormone. In English.

*Le Enervazioni Articolari.* By F. Moria and F. Roasenda. (Pp. 138, 1,400 lire.) Turin: Minerva, 1948.

An account of innervation of the joints for the surgeon.

*The 1948 Year Book of Radiology.* Edited by Jenner Hodges, M.D. and I. I. Kaplan, M.D. F.A.C.R. (Pp. 472, 36s.) London: H. K. Lewis, 1948.

Abstracts from recent papers on diagnosis and therapy with editorial comment.

*Die Reaktion der Pupille auf Mydriatica nach Unterbrechung der Sympathischen Pupillenhahn.* By P. Wornser. (Pp. 160, 17 Swiss francs.) Basle: S. Karger, 1948.

An analysis of pupillary reactions to mydriatics after interruption of the sympathetic innervation.

*The Countryman Book.* Compiled by J. W. Robertson Scott, C.H. (Pp. 308, 10s. 6d.) London: Odams Press, 1948.

A selection of articles of rural and horticultural interest from the *Countryman*.

*Traitement des Dermatoses Communes.* By A. Desaux. (Pp. 1,300, 1,960 francs.) Paris: Masson, 1948.

A textbook intended for the general practitioner or young specialist.

# BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 4 1948

## THE KING'S HEALTH

The medical profession in Britain has shared to the full the universal alarm felt about the state of the King's health. His medical advisers in the bulletin issued on Nov. 23 stated that 'the King is suffering from an obstruction to the circulation through the arteries of the legs, which has only recently become acute, the defective blood supply to the right foot causes anxiety'. The King's doctors underlined the gravity of the news in the bulletin when they stated that "it would be hazardous for His Majesty to embark upon a long journey, which might delay his recovery and which might well involve serious risk to a limb. On Monday of this week a further bulletin brought better news of an improvement in the general health of the King, an important factor in re-establishing arterial circulation to the feet, which is also being encouraged by appropriate medicinal and physical measures. The King's doctors state that there is less cause for immediate anxiety regarding the right foot.

The medical profession will join with the rest of the community in heartfelt sympathy with the King in his present disablement—a sympathy heightened by their knowledge of the pathology of arterial disease. The British Medical Association in particular will wish its Royal Patron a speedy return to better health.

## VIRUSES OF HEPATITIS

There is now no doubt that a certain number of persons in apparent health carry with them in their blood stream a virus which when inoculated parenterally into other healthy human beings will produce in a proportion of cases the signs and symptoms of hepatitis. Evidence that such a virus existed first appeared in 1934 shortly after the introduction of immunization against yellow fever, when the vaccine was made up in pooled serum obtained from presumably healthy persons<sup>1</sup>. Shortly afterwards Soper and Smith<sup>2</sup> in South America also reported the occurrence of hepatitis after the administration of yellow fever vaccine, and McNally<sup>3</sup> drew attention to the fact that the disease had been observed in children and adults who had received inoculations of pooled measles immune serum. Thus even before the war the possibility was recognized that serum from apparently healthy persons might contain an heterogenic agent<sup>4,5</sup>. Unfortunately neglect of this possibility led to much illness in the American armed Forces<sup>6</sup>.

while among British Service men and women inoculated in this country nearly 800 cases are known to have occurred. Since human serum has been discarded in the preparation of yellow fever vaccine some hundreds of thousands of persons have been inoculated without the development of a single case of hepatitis.

Meantime there were other pointers to the presence of a virus in human blood and its products. Service and his colleagues<sup>7</sup> in Russia noticed the development of jaundice in persons inoculated with a vaccine against sandfly fever, the vaccine contained human serum. Beeson<sup>8</sup> in 1943 described hepatitis appearing one to four months after the transfusion of blood or plasma. The disease has also been known to follow the giving of blood or its products as a prophylactic against mumps<sup>10</sup> and when therapeutic malaria has been induced by the injection of red cells infected by malaria parasites<sup>11,12</sup>. Further presumptive evidence that a virus was present in the blood stream had been derived from the experience of venereal disease clinics in the years between the two world wars. The common belief, however, was that the jaundice was due to arsenic acting on a liver damaged by syphilis, despite the fact that hepatitis was known to occur in patients who had received only bismuth, in patients given injections of acriflavine,<sup>13</sup> and in diabetic clinics<sup>14</sup>. In a survey of the information available on the incidence of arsphenamine jaundice in 1939 Findlay<sup>15</sup> reached the conclusion that some factor other than these drugs was necessary for its development, and that this factor was a virus and quite possibly the virus of infective hepatitis.

The suggestion that a virus was responsible for the production of "syringe-transmitted hepatitis," as it was called, was again made in 1943 by MacCallum<sup>16</sup> and Bigger<sup>17</sup>. Later MacCallum<sup>18</sup> showed that serum from a patient with so-called arsenical jaundice would produce hepatitis in normal volunteers who were not receiving arsenic or any other drug. Since then it has become evident that if carefully sterilized syringes are not used for each individual there is a risk of transmitting hepatitis by giving intramuscular injections of penicillin or even by simple venepuncture. The presence of a hepatitis-producing virus in the blood stream has now been demonstrated throughout Europe, Russia, North and South America, and in various parts of Africa, including Egypt, Uganda, and West Africa<sup>19</sup>.

While these are known facts, there is still room for speculation. Is this virus which is present in the blood stream of perhaps 5%, or it may be even 10%, of apparently healthy persons the same as the virus of infective hepatitis? Though the signs and symptoms of the hepatitis following yellow fever vaccination were indistinguishable from those of infective hepatitis the incubation period was

nuch longer—58 to 134 days, as against 15 to 35 days for infective hepatitis<sup>14</sup>. Further, the disease tended not to infect contacts. The histological changes in the liver were indistinguishable,<sup>20, 21</sup> and neither virus can be transmitted to laboratory animals. However, there have now been outbreaks such as those recorded by Smith and Hall<sup>12</sup> and Capps and his colleagues<sup>22</sup> in which the incubation period was in every case quite short (17 to 43 days), other similar outbreaks are known. Aycock and Oren<sup>23</sup> suggest that the prolonged incubation period of syringe-transmitted hepatitis is due to the presence of immune body together with virus in the inoculum. Although syringe-transmitted hepatitis is not as a rule highly infectious there are instances where contact cases of jaundice are very difficult to explain except by spread of infection<sup>24, 7</sup>. Some outbreaks of infective hepatitis in schools, however, have been limited to one or two cases. More recently it has been found that infective hepatitis virus is present in the stools, and in the urine also when haematuria occurs. The virus which is present in the blood stream in syringe-transmitted hepatitis does not appear to be present in the stools, though it conceivably might be if the patient suffered from haemorrhage from the bowels or even from bleeding piles. So far no instance has been published of infection with the blood-borne virus by the alimentary route, whereas infective hepatitis can be readily transmitted orally. Cross-immunity experiments are contradictory in some immunity to the two viruses appears to develop, in others no immunity. But it must be remembered that the immunity to infective hepatitis is by no means absolute, and cases of a second attack are not uncommon.

This uncertainty whether two separate viruses or strains of one and the same virus are concerned is reflected in the question of nomenclature. There is no doubt about the nomenclature of infective hepatitis: this term was first used by Cockayne<sup>25</sup> in 1912 and thus has priority over "infectious" or "epidemic" which was first used by Lindstedt<sup>26</sup> in 1919. The term "homologous serum jaundice" was used for the disease caused by the blood-borne virus in 1943 in a memorandum prepared by medical officers of the Ministry of Health<sup>10</sup>. Since then a fuller knowledge of the disease has been obtained. The word "jaundice" is unfortunate for clinical jaundice may be either slight or absent. The fundamental lesion is a hepatitis, so that "homologous serum hepatitis" or, as it has been called in America, "SH disease" would be preferable. But the word "serum" is open to criticism, for the infection is transmitted often by plasma and sometimes by whole blood as well as by serum. Findlay<sup>27</sup> suggested the provisional term "haematic," which was preferred to "haematogenous" because the latter suggests that the virus is actually produced in the haemopoietic system.

If the natural method of transmission of haematic hepatitis was known with certainty it might be possible to take more reasonable steps to prevent it. It does not seem to be transmissible by food, but there is evidence that it can

infect through the nasopharynx<sup>27, 28</sup>. At present we have no means either of preventing natural infection with haematic hepatitis or of determining who is a symptomless carrier of the virus. It is known that after an infection some viruses, such as that of anaemia of horses, remain in the blood stream for life. Whether this is true of the haematic viruses is not yet known. The prevention of haematic hepatitis has two aspects: (1) prevention of cross infection from the use of contaminated syringes and needles, and (2) avoidance of infected blood or its products in transfusions or therapeutic immunizations. In clinics and wards where repeated injections have to be given, often with a limited number of syringes, the only way of avoiding haematic hepatitis is always to clean and boil syringes and needles before each injection. If these steps are correctly carried out there will be no cases of hepatitis. That it is possible to make mistakes even with apparently foolproof techniques is clearly shown in the papers which we published last week by Malmros and his colleagues (p. 936) in Sweden and by Morton (p. 938) in this country. It is only when all concerned in the sterilization of syringes and needles fully realize the necessity for scrupulous care that it will be possible to abolish syringe-transmitted hepatitis.

The selection of uninfected blood, plasma, or serum for transfusion or immunization is a more difficult matter, since there is no indication of who is or is not a carrier of a hepatitis virus. The danger of hepatitis has not always been fully appreciated by those who collect blood from volunteers. Thus in some instances blood has been taken in areas where an outbreak of infective hepatitis was occurring, while persons who have had hepatitis have acted as donors, having been told that if the disease occurred two years previously there was no danger. For this statement there is of course no scientific evidence, since it is not known whether after an attack virus may not at times recur in the blood. By limiting pools of whole blood or plasma to 10 donors it is possible to some extent to limit the distribution of haematic hepatitis virus if the incidence of infected donors is below 1 in 10.

Since the virus may apparently be inactivated by ultra-violet light Wolf and his co-workers<sup>29</sup> gave irradiated plasma to 21 volunteers without untoward reaction, but they offered no evidence to show that the virus was actually inactivated. MacCallum<sup>30</sup> failed to inactivate the virus with the doses of ultra-violet light recommended by Oliphant and Hollaender,<sup>31</sup> but Blanchard and his colleagues<sup>32</sup> have now shown that a practical and effective method of irradiating icterogenic serum and plasma can be evolved. Irradiation cannot of course be applied to whole blood. Gellis and his co-workers<sup>33</sup> used heat in an attempt to inactivate hepatitis virus. Certain viruses (Theiler's mouse encephalomyelitis virus, vaccinia, tobacco-mosaic, and tobacco-necrosis virus) added to pooled plasma

survived fractionation and were found in all fractions prepared from plasma. Albumin solutions to which the haemagglutinating hepatitis virus was added were heated at 60° C for 10 hours and when inoculated into volunteers failed to cause hepatitis, whereas the unheated mixture of albumin and virus caused hepatitis, though without jaundice, in volunteers. This method of heat inactivation may be applied to albumin solutions, since they can be stabilized to withstand heating, it is not of course applicable to serum, plasma, or whole blood.

Initial studies suggested that gamma globulin injections might be of value in preventing the onset of haemagglutinating hepatitis, but more recent investigations<sup>31, 36</sup> showed that one injection was valueless. Since there is evidence that passive immunity resulting from the injection of gamma globulin does not last for more than three weeks and the incubation period of haemagglutinating hepatitis may be as long as three months, a series of injections would probably be necessary. Further the large scale use of gamma globulin would be difficult in a civilian population. It is obvious that much more work requires to be done on the hepatitis viruses. Rosenthal<sup>37</sup> found that 40.8% and Brightman and Korn<sup>38</sup> 4.5% of transfused patients developed hepatitis. More blood and blood products are now being used for transfusion than during the war, and the need for increased knowledge is urgent.

## TREATMENT OF INFANTILE ENTERITIS

The announcement early this week that a gastro-enteritis "flying squad" is now based on the Hospital for Sick Children, Great Ormond Street, and ready to work, has roused the interest of the public in this dangerous disease. Deaths from gastro-enteritis in infants under one year of age have exceeded 3 000 per annum since 1940, giving mortality rates which have varied from 4.4 to 5.2 per thousand live births. The increase in the number of deaths in the past few years (3,611 in 1946) is doubtless related to the increased number of births and to the overcrowded and unhealthy houses in which many babies are being reared, for infantile enteritis is a social disease with its greatest incidence among artificially fed infants living in poor-class urban areas. Unfortunately, because this infection is not generally notifiable, our knowledge of its epidemiology is limited, although the investigation by the Wrights<sup>1</sup> was a brave attempt to disentangle some of the environmental factors concerned in its aetiology. Meanwhile the search goes on in the laboratory for a specific causal organism. Here again progress is hampered because the material admitted to hospital may consist of a variety of clinical syndromes varying from simple dietetic upsets, through enteritis associated with some parenteral infection, to primary gastro-enteritis. It is therefore more profitable to concentrate laboratory investigations on localized institutional outbreaks or on more widely spread epidemics. In such an epidemic which occurred in Aberdeen in the spring of 1947 the labours of the bacteriologists along a

novel approach have been rewarded. Giles and Sangster<sup>2</sup> prepared agglutinating antisera from three strains of *Bact. coli* (biochemically identical with *Bact. coli* No. 1) isolated from three fatal cases and found that these strains were all serologically alike. Furthermore, 86 strains of *Bact. coli* out of 92 isolated from cases of primary gastro-enteritis were agglutinated by the specific antiserum, whereas this serological type of *Bact. coli* was isolated from only 2 out of 44 cases classified as enteritis secondary to some parenteral infection and from 3 out of 72 mild cases of infantile diarrhoea not treated in hospital. The organism was also found in the faeces of four infant contacts who 24 hours later developed diarrhoea; it disappeared from the faeces of affected infants as they recovered from the infection. These findings corroborate the earlier work of Bray,<sup>3</sup> and indeed the authors state that their organism closely resembles Bray's strain serologically, but in view of claims made from time to time for the aetiological relationship of other intestinal bacteria such as Morgan's bacillus, proteus and paracolon, *Staph. aureus*, and *Str. faecalis* a certain caution is necessary in their interpretation. The results obtained by other workers in this field will be eagerly awaited.

While the aetiology still remains unsettled, considerable advance has been made in the treatment of infantile enteritis. Acute vomiting and diarrhoea in an infant lead quickly to dehydration and an upset in the balance of body fluids which, if allowed to progress beyond a certain stage, become irreversible. The primary need therefore is to prevent or correct dehydration either by direct treatment and control of the diarrhoea and vomiting or by the replacement of lost body fluids. There have been many "cures" of gastro-enteritis aimed directly at the alimentary tract, either to reduce peristalsis, absorb toxins, or eliminate the infecting organism. In the last category the poorly absorbed sulphonamides—e.g., sulphaguanidine and "sulphasuxidine"—have proved disappointing, though they still have a vogue on the Continent. New antibiotics like aerosporin and streptomycin are now being used, and while in one study encouraging results have been reported with streptomycin<sup>4</sup> it is still too early to say what part these intestinal bactericides will play in the treatment of gastro-enteritis. Certainly they cannot be expected *per se* to correct severe dehydration and shock. Therefore effective treatment of the acute case of infantile enteritis must surely depend primarily on rehydration in a way that will establish the proper balance of body fluids and osmotic pressure as quickly as possible and supply food until the alimentary system is again functioning normally. Subcutaneous or intraperitoneal glucose-saline may suffice in mild cases, but for the acutely dehydrated child, who is usually in a toxic or "shocked" condition, intravenous infusion of a Hartmann-glucose solution alternating with serum or plasma is essential.

The setting up of an intravenous drip and its maintenance for two or more days require experienced doctors and nurses. It has become the firm conviction of those engaged in the day-to-day treatment of infantile enteritis that satisfactory results will be obtained only in

special units with adequate accommodation—preferably as single-bedded rooms, for relapses from cross-infection are not uncommon—and enough trained nurses in the charge of an experienced medical officer. The organization of such a unit is described by Dr M B Alexander elsewhere in this issue, and the results obtained—22 (8.5%) deaths among 258 dehydrated infants under one year of age—are a tribute to the teamwork of medical and nursing staff under conditions that were by no means ideal. Dr Alexander makes the interesting point that the case mortality in the four consecutive six-monthly periods following the establishment of the unit was respectively 11.3%, 2.4%, 2.4%, and 3.5%, which suggests that treatment becomes more efficient after the nurses gain experience in the handling of cases. When these results are compared with the fatality rates of 30%–60% which are still being experienced in different parts of the country and with the tragic reports of even higher rates in institutional outbreaks, the need for properly organized units for the treatment of gastro-enteritis becomes obvious. Large established units which could give experience to a maximum number of doctors and nurses in the minimum of time might be used as training centres for the medical officers and sisters who are to take charge of new units. They would thus become conversant with the organization and management of a going concern. Alternatively, a demonstration team could be sent to a hospital to help in establishing a new unit and to initiate medical and nursing staff into the intricacies of intravenous drips and the like. The newly organized flying squad at the Sick Children's Hospital, Great Ormond Street, has been written up in the lay press as something akin to a fire brigade, ready to fly at a moment's notice to quench some conflagration in the shape of an outbreak of gastro-enteritis. An equally useful function may be to act as a demonstration team by taking over the treatment of gastro-enteritis for some weeks in a hospital where it is proving troublesome, and thereby training the resident staff in the proper handling of this disease. We understand that the flying squad would regard this as one of its main purposes, and it is to be hoped that hospitals which are experiencing high fatality rates among infants admitted with diarrhoea and vomiting will make use of this service. The family doctor will play his part by not sending patients with mild dietetic disorders to hospital and by doing all in his power to encourage the continuance of breast-feeding when babies are reared in conditions where the standards of household hygiene and infant care are poor.

### O RUSSIA! O MORES!

In a review in *Nature* in 1946<sup>1</sup> Professor Eric Ashby wrote "As to the present state on the new genetics in the Soviet Union, it is safe to assume that Lysenko's school is well past its zenith." A year later, however, the Russian geneticist Zhebrak was severely taken to task by *Pravda* for daring to express his own views of Lysenkoism. 'Zhebrak' *Pravda* pontificated, 'as a Soviet scientist

should have unmasked the class meaning of the struggle which is taking place around questions of genetics. But, blinded by bourgeois prejudices, by detestable fawning on bourgeois science, he has adopted the attitude of the enemy's camp." Reviewing the situation in a leading article in these columns in the *Journal* of Oct 18, 1947, we observed that this attack by *Pravda* suggested "that genetics is once again becoming an acute political issue in the USSR." And now a year later the Lenin All-Union Academy of Agricultural Sciences has declared that the genetics of Lysenko is the only genetics that may be taught in Soviet institutions,<sup>2</sup> a decision which a special correspondent in *The Times*<sup>3</sup> says "has shocked scientists all over the world." Sir Henry Dale, O.M., President of the Royal Society from 1940 to 1945, has made his protest by resigning his honorary membership of the Academy of Sciences of the USSR. Sir Henry points out that it is clear from Lysenko's own statement "that his dogma has been established and enforced by the Central Committee of the Communist Party as conforming to the political philosophy of Marx and Lenin." Sir Henry Dale might have added as a footnote to his letter a statement made by Professor J. B. S. Haldane to a correspondent of the American magazine *Time*: "I don't think a political body should decide scientific theories."<sup>4</sup>

Dreary conformity to the deadening dogmas of the Marxist faith is being imposed on those unfortunate countries now being absorbed into the Russian Empire. This year the Czechoslovak medical association was decreed out of existence, and now doctors, nurses, and midwives in the Polish medical schools are obliged to take courses in dialectical materialism. The Polish Vice-Minister of Health has declared that "the philosophy of Marxism is an indispensable tool in the practical and scientific work of a physician." The basis of Polish medical schools, it is declared, must be "class consciousness and systematic political training."<sup>5</sup> As an example of how the Russian medical man has to pander to the Russian propaganda machine we may note the observations made by Professor S. A. Reinberg in an article<sup>6</sup> on mass radiography in the Soviet Union. Professor Reinberg is Director of the Molotov Central Institute for Scientific Investigation in Radiology. He notes that the number of radiography examinations made is "still less than those of some foreign series," and then goes on to explain this away by stating "There is no doubt that these pretentious figures published in foreign countries constitute only a thinly disguised cheap advertisement." Mass radiography, says Professor Reinberg, "by its very nature is foreign to the ideas and training of the medical faculty in capitalist countries. The idea of radiography of large masses of workers does not correspond to the interests of a bourgeois society." This kind of nonsense, and the tragedy of death and exile of Soviet geneticists, must, we are sure, be silently condemned by countless men of medicine and science in the USSR. With them we must hope that the day is not far off when freedom to think and to speak and to write is once more restored to a great people.

### TEMPERATURE RECORDING

In 1620 Sir Francis Bacon wrote, "Let further inquiry be made into the different degrees of heat in different parts and limbs of the same animal."<sup>1</sup> But very few studies of skin temperature were made till the nineteenth century, when Davy<sup>2</sup> investigated the problem in 1814. Others followed him, using the mercury thermometer, and later Becquerel

<sup>2</sup> Quoted by Cobet R. *Ergebn. Physiol.* 1926 25 440

and Breschet<sup>3</sup> in 1835 and Geigel<sup>4</sup> at Wurzburg made more accurate studies with the thermocouple. Geigel took measurements in four different areas and compared them with the rectal temperature taken simultaneously. He showed that during a rigor the surface temperature falls while the rectal temperature rises, the difference between the two readings therefore increasing. In 1931 Fritz Talbot published his monograph on skin temperatures in children. Using the thermocouple he made the following observations: variations occur in the temperature at any given spot on the body within five minute periods; there are considerable differences in the temperature of the skin in different parts of the body, the temperature of the trunk being highest, that of the face next, and of the extremities lowest; the surrounding temperature has a considerable effect on the skin temperature, the cooler the room the cooler being the temperature of the skin; there is a rapid loss of heat from the surface of the body on exposure; exercise causes a preliminary fall followed by a rise of skin temperature; and other factors such as sleep and clothing affect the temperature. He confirmed the well-known fact that the rectal temperature is higher than that of the skin, and more recently<sup>6</sup> he has shown that the rectal temperature varies with the depth of insertion of the thermometer. It should be inserted 5 cm in infants, the reading at 14 cm will be 0.2–1.3° C higher than if it is inserted 2–6 cm. It is worth noting that the rectal temperature may not always be higher than the oral. Rappaport<sup>7</sup> described a series of 25 patients whose rectal temperature was normal but in whom the oral temperature was raised persistently above normal. The reasons for this unusual finding are obscure.

Elsewhere in this issue Professor Alan Moncrieff and Dr B J Hussey describe some simple experiments with the ordinary mercury thermometer. They mention the well-known fallacy of the 'normal' axillary temperature: the child is chilled in the out-patient department, but when he has been warmed in bed a raised axillary temperature may be recorded within half an hour of his admission to the ward. The ordinary half-minute thermometer placed in the axilla gave a reading 0.4–1.4° F (0.22–0.78° C) higher after five minutes than after two minutes. Because of the unreliability of readings taken in the axilla or groin the authors advocate that these sites should no longer be used for temperature recording, and they recommend that temperatures should be taken rectally in all children under five years and by the mouth after this age. Allowance must of course be made for the fact that the rectal temperature is normally higher than that in the mouth. With proper technique the risks of cross-infection are small. Green and Penfold<sup>8</sup> recently investigated the risk of transmitting infection by hospital thermometers and paid special attention to the efficiency or otherwise of the antiseptic solutions in common use. They obtained on culture up to 40,000,000 organisms per ml, including *Bact. coli*, from glycerin of thymol solution into which thermometers had been dipped on the nurses' rounds, but no organisms from 1 in 20 phenol. Every child should have its own thermometer kept in a safe antiseptic solution above the bed or in a cupboard; it should be sterilized when the child is discharged.

Taking the temperature is a simple procedure—so simple that frequently insufficient care is taken, particularly in the choice of site in inserting the thermometer properly, in

leaving it in for a sufficient length of time (at least two minutes for a half-minute thermometer), and in sterilizing it after use. We are prepared for technical errors in complicated laboratory tests but often forget the possibility of errors in simple bedside procedures.

### THE MILK BILL

Last week the Government introduced into the House of Lords the Milk (Special Designations) Bill. This will give the Minister of Food power to specify areas in which only specially designated milk may be sold retail or supplied under the milk-in-schools scheme. The approved designations in England and Wales will be T.T. (certified) milk, T.T. milk, accredited milk (derived from a single herd), pasteurized milk, and sterilized milk. In Scotland the designation "standard" takes the place of "accredited". Descriptions of these milks and the conditions which must be complied with before they can be so designated will be set out in Milk (Special Designations) Regulations.

In a recent annotation<sup>1</sup> we drew attention to Lord Bledisloe's observation that Great Britain, with about 40% of her cattle infected with tuberculosis, has the worst record in this respect of all the countries in Western Europe. Milk must be made safe for the public to drink, and at the same time the health of dairy herds must be improved. The Minister of Agriculture bears responsibility for the latter task, but the Minister of Food under the new Bill is now to be given power to ensure that only heat-treated milk or milk from disease-free animals may be sold in certain areas of the country. It has often been suggested that the public might be misled by the term "accredited" into thinking that milk from accredited herds must be "safe," and it is encouraging to see in the new Bill that recognition of accredited and standard milk as designated milks will be restricted to a period of five years from the commencement of the Act, and that in the meantime the designation will apply only when the milk concerned comes from a single herd. Many would wish that it might have been possible to dispense with this designation immediately. In order that the Minister of Food may be in a position to carry out the requirements of the Bill he is to have power to install and operate heat-treatment plants wherever he may decide they are necessary, or he can arrange for the work to be done by local authorities.

Under Defence Regulation 55G (now to be revoked) the Government has had powers for the past five years to impose limitations similar to those proposed in this Bill. So far as we are aware, no area of the country has yet been specified as an area in which only designated milk may be sold. Shortage of heat-treatment plant and of skilled labour cannot be the only reasons for this deplorable gap during which many lives have doubtless been lost and much illness caused by infection with bovine tubercle bacilli. With the powers proposed in this Bill the Minister of Food should at last be in a position to correct what is recognized by the medical profession to be a serious hygienic defect in this country.

The Goulstonian Lectures on 'The Cardiology of Old Age' will be delivered by Dr C J Gavey, FRCP, before the Royal College of Physicians of London (Pall Mall East S.W.) on Tuesday and Thursday Jan 11 and 13, 1949, at 5 p.m.

## LOYAL ADDRESS OF THE BRITISH MEDICAL ASSOCIATION

We print below the loyal address presented to His Majesty the King Patron of the British Medical Association on the occasion of the birth of a son to Her Royal Highness Princess Elizabeth

To the King's Most Excellent Majesty

The Humble Address of the President and Members of the  
British Medical Association

May It Please Your Majesty,

We, Your Majesty's dutiful and loyal subjects, the members of the British Medical Association distributed throughout Your Majesty's Commonwealth and Empire, humbly offer to Your Majesty and to Her Most Gracious Majesty the Queen congratulations on the birth of a son to Her Royal Highness the Princess Elizabeth, Duchess of Edinburgh.

Our gladness on this auspicious occasion is joined with a fervent hope that the young Prince may enjoy length of days richly blessed with happiness and health.

With our heartfelt felicitations we beg to express to Your Majesty our high and affectionate regard and to assure Your Majesty of our unceasing fidelity and loyalty to Your Majesty's Throne and Person.

Signed on behalf of the British Medical Association

LIONEL WHITBY, *President*

H GUY DAIN *Chairman of Council*

F A GRIGG *Chairman of the Representative Body*

A M A MOORE *Treasurer*

## Reports of Societies

### PREVENTION OF ACCIDENTS

The prevention of accidents was the theme at a meeting of the Section of Epidemiology and State Medicine at the Royal Society of Medicine, held on Nov. 1 with Sir Allen Dray in the chair. Mr W GISSANE, surgical director of the Birmingham Accident Hospital, discussed the incidence, severity, and after effects of accidents domestic and industrial with special reference to the provision of efficient treatment and showed that despite some improvement there was no room for complacency. He thought that patients with accidental injuries endangering life were too often given treatment too late or by medical personnel inadequately trained for the task. Suitable structural arrangements and modern equipment were required in hospitals for this purpose, and team work was necessary for even reasonably good results. Adequate after-treatment should be given by the same team. As a result, crippling deformities which in the past lowered industrial efficiency were rare and the effect of treatment was greatly improved when patients received rehabilitation specially designed to fit them for a particular task or occupation. He felt that while prevention of accidents might be a very difficult problem the prevention of the crippling results was something which could be tackled immediately.

Dr FREDERICK COLLINGWOOD gave an interesting analysis of 70 cases of accidents treated in Birmingham. Of these 504 occurred in the home (all ages) and 232 in industry. The fatality of the home accidents was six times that of the industrial accidents and the average stay in hospital was approximately 26 longer—due largely to the more serious accidents occurring in the home, especially burns and scalds in children and old people. One third of the patients burnt at home were crippled and the burns were caused mainly by tea and other kettles, coal fires, electric and gas fires, baths left unattended and inflammable liquids. Electrical faults and gas burners constituted a very small part. The need for first aid and admission to hospital without prior treatment apart from the removal of the damaged member was stressed as part of the first aid.

### The Danger of Carelessness

Dr C A BOUCHER stated that more than 8000 persons were killed every year in England and Wales as a result of accidents at home and in everyday pursuits. Six thousand of these were in the home, which represented about two fifths of the total of all fatal accidents including road accidents, transport accidents, mine accidents etc. There had been no fall in the figure since 1938. On the contrary, in the age groups under 5 and over 65 there had been an increase. In 1945 one fifth of all fatal accidents occurred in children under 5 and about half in persons over 65, falls being the main cause in the latter group. Structural defects in the home or faulty house design were not considered to be a major cause. On the other hand, overcrowding in the home was a definite factor, especially in the case of accidents affecting children. Dr Boucher laid emphasis on carelessness and neglect about the dangers existing in the home and the use of faulty appliances which looked tempting and cheap in the shops and could be purchased so easily by the non-discriminating person. He felt that there was a great lack of awareness among the people concerning the extent of this problem. There was also indifference, when it was realized that the majority of these accidents were preventable. He believed that there were at last signs of activity directed towards the prevention of home accidents. The Royal Society for the Prevention of Accidents had shown great energy and imagination in drawing the attention of the public to dangers in the home. This society was the chief medium through which educational work was initiated. There was also an Inter-departmental Committee on Accidents in the Home set up by the Home Secretary in 1947 to co-ordinate the work of departments in preventing accidents in the home, and a Domestic Accidents Panel of the Building Requirements Subcommittee of the Ministry of Works was already at work.

In Dr Boucher's opinion the most hopeful course was to use education and propaganda rather than legislation. He quoted the ineffectualness of the provision in the Children and Young Persons Act 1933, in which it was decreed that any person over the age of 16 having the care of a child under the age of 7 who was killed or seriously injured because of an insufficiently guarded open fire, shall be liable to a fine of not more than £10. Nobody could penalize a woman, particularly a mother for so tragic an accident. He thought that the aim of education should be to make the public critical of goods which they bought in the hope that in time public opinion would demand safe articles, in the schools teachers could help by giving suitable instruction to children.

### Need for Reliable Statistics

Dr PETER STOCKS, mentioning the work being done in America to reduce home accidents, thought that general appeals were unlikely to succeed and that each cause of accident would have to be attacked in detail. A necessary prelude to such action was to obtain good statistics, and the General Register Office was doing three things to that end. Coroners' certificates were providing more detail than hitherto of the circumstances of fatal accidents and the places where they took place. After lengthy discussion with experts in the U.S.A. a classification both by nature of injury and cause of accident had been grafted into the International List, which was now designed for morbidity as well as mortality statistics. This contained definitions and enough detail of grouping to satisfy anyone. The teaching hospitals had in the past paid little attention to causes of accidents but now they were being asked to do so in the interests of prevention. It was hoped to secure sufficient information about in-patients during 1949 to provide some useful statistics. He believed that the hospitals could in that way make an important contribution to the eventual reduction of many kinds of accidents.

Dr BRIAN STANFORD gave a preview of a new film strip lecture addressed to persons who have the care of children. This showed the main causes of home accidents and the ways in which they could be prevented. Mr JOHN BUNNAN described a bag which could be used to cover a limb and thus provide adequate protection until the injured patient reached medical care.

## Correspondence

### Treatment of Placenta Praevia

SIR—The excellent paper by Mr W G Mills (Nov 20 p 896) in which 100 cases of placenta praevia are recorded with no maternal deaths and a foetal and neonatal mortality of 16.5%, provides further convincing evidence of the value of expectant treatment of this disease and shows that it can be carried out in proper surroundings with safety to the mother and increased chances of survival for the child. I have advocated this treatment for 20 years or more and described it in the first edition of my book, *Antenatal and Postnatal Care* (1935) London and during that time it has been practised in the obstetric unit of University College Hospital London.

It is encouraging to note that Mr Mills adopts the newer classification of placenta praevia into four degrees in preference to the older and confusing one into lateral, marginal etc. On one point, the treatment I have advocated views differing from his—i.e. that once a "warning" haemorrhage has occurred after the 28th week the patient should be kept in hospital under observation until delivery. The majority go into labour spontaneously at term deliver themselves without further bleeding and go home without any exploration of the lower uterine segment having been made, and consequently without the nature of the haemorrhage—whether unavoidable or accidental—having been accurately ascertained. Only a speculum has been passed shortly after admission to view the cervix and exclude any cervical lesion. In this annual report of University College Hospital such cases are classed as 'haemorrhage of unknown origin,' and four varieties of antepartum haemorrhage are included (1) haemorrhage certainly due to placenta praevia, in which the placenta has been *felt* or *seen* in the lower segment, (2) those in which it is not felt or seen there (accidental haemorrhage), (3) those due to haemorrhage from extra-placental sites usually the cervix, and (4) those in which it is not known if the haemorrhage is accidental or unavoidable. The last is by far the largest class in each annual report. In other words the report is an honest one not attempting to classify where accurate classification is impossible.

Some other hospitals have already adopted this classification but it is disappointing to find that in the recently published 'standard' form for annual reports (*J Obstet Gynaec Brit Emp*, 1948, 55, 478) drawn up by a committee of the Royal College of Obstetricians and Gynaecologists the old one into three varieties only is adopted. Frankly I am always suspicious, to put it mildly, of any report that classifies all cases of antepartum haemorrhage as due either to placenta praevia or to premature separation of a normally situated placenta (accidental haemorrhage). Into what class the case is put so often depends on the whim of the house surgeon or registrar, or on examination of the placenta after its delivery—an entirely unreliable guide, as experience proves.

The expectant treatment often means that patients have to be kept in hospital for several weeks before delivery but all who have practised the method will agree that it is well worth while. It makes too a great demand on antenatal beds but bed scarcity is no reason for condoning inadequate antenatal care. If we do not in the interests of our patients, demand more antenatal beds we shall certainly never get them—I am, etc.,

London W 1

F J BROWNE

SIR—Whilst congratulating Mr W G Mills on his results of treatment of placenta praevia (Nov 20 p 896) I should like to point out that his figures are not comparable with other statistics. Vaginal examination under anaesthesia is now practised in some obstetric centres in all cases of antepartum haemorrhage after the thirty-sixth week of pregnancy unless the bleeding is of extraplacental origin. I gather that this is the routine at the Birmingham Maternity Hospital.

Such a practice results in accuracy of diagnosis and successful results but it also gives a diagnosis of placenta praevia to a proportion of that large group of cases which Professor F J Browne includes under the heading 'antepartum haemorrhage of unknown origin'. Now this group comprises those cases

of haemorrhage which are mild and the majority of them end in a spontaneous and successful delivery. If cases of placenta praevia from this group are added to statistical summaries it will improve the maternal and foetal death rates. This may in part account for the apparent success of Mr W G Mills's results—I am, etc.,

J G DUMOULIN

### Primary Post-partum Haemorrhage

SIR—I have only just seen the *Journal* of Oct 23, but I would like to comment on the article by Drs James B Joyce and G Gordon Lennon at p 740 of that issue. It is stated, 'We believe it is better to go to the highest point of the placenta and start separation from above downwards.' It seems to me that a placenta situated on the posterior wall would be extremely difficult to remove by this method. It would mean the operator working with an acutely flexed wrist in the confined space of the uterine cavity. This would create a tremendous mechanical disadvantage as well as causing the hand to become quickly exhausted if the operation takes longer than anticipated. It would also mean introducing far more of the hand, wrist, and forearm into the uterine cavity than is necessary.

The reason given in support of this method is that the uterus can retract immediately on the open sinuses. Surely with adequate control of the fundus with the external hand there is not much chance of venous bleeding occurring while the operation is actually being carried out. With an operation such as this, in which one has always to work alone and in the dark, it seems a pity to confuse the first time operator (who is often considerably in awe of the whole procedure) with theoretical directives, however explicit. All this apart from the fact that it is much easier to remove a placenta from below upwards.

The authors include interesting quotations from obstetric forebears, consequently it seems doubly hard on Crédé that his name should be omitted deliberately, and so unceremoniously, from Part II. The reason given, that he never awaited the natural separation of the placenta before applying his method, seems irrelevant. Crédé may have been an impatient man, but surely the technical method is the same at whatever moment after delivery of the child it is carried out—I am, etc.,

ROBERT A H KINCH

### Breast-feeding

SIR—I read with interest Dr Enid L Hughes's article on breast feeding (Sept 25, p 597). In the fishing community of Newfoundland marriage, having babies, and breast feeding are looked upon as natural for a woman. As a result the mothers have a very much easier time while having their babies than do their sisters in England. Dr Grantly Dick Read's teaching is not needed here, for mothers accept their labour as something essentially normal, not something to be feared and struggled against as in England.

Likewise with breast-feeding. In the houses there is rarely any possibility of privacy, but the mother feeds her baby in full view of her family and any visitors who happen to be present. While waiting to see the doctor it is quite common for the mother to give her infant a "meal". At least 95% of the babies are breast-fed, and a woman who does not breast feed is looked down on.

Unfortunately the above does not obtain in the towns where the situation is the same as in England—giving birth is a 'disease' and breast feeding is carried on by a much smaller percentage. It would be of interest to conduct a survey of breast feeding considering the social status of the family—I am, etc.,

Burgeo Newfoundland

M G JACOBY

SIR—The figures given by Dr Enid L Hughes (Sept 25 p 597) regarding failure of lactation raise the question how important this is. After 19 years in M and CW work my views have changed and I do not now regard artificial feeding as a disaster. On the contrary, I think the gains to mother and child are many. The mother is relieved of a function

which is an irksome tie and often detrimental to her health, and the baby, brought up on dried milk preparations fortified with vitamin D and minerals, plus cod-liver oil and orange juice, receives a diet lacking nothing needful for its optimum development. In fact, at the five year-old routine school inspections I have often remarked that the children with the best teeth have been artificially fed and, contrariwise that the worst dentition tends to be correlated with breast feeding, particularly if this has been prolonged.

Moreover, the teaching that breast milk is a perfect diet is, we now know, fallacious and often results in the withholding from the infant of the necessary vitamins, iron, etc. We do not know the ideal length of time for breast-feeding, but it is probably much shorter than the fashionable 6 to 9 months. As for the loosening of the emotional tie between the lactating mother and her infant, this I think is ideological. I have never noticed any diminution of affection in the mother or of satisfaction in the infant when bottle feeding is instituted. On the contrary, when the babe is partly breast-fed and partly bottle-fed the mother almost invariably says it prefers the bottle to the breast.

In short, during the puerperium and for a few weeks following I think breast-feeding is desirable if it can be achieved. But it is a primitive function which the majority of women find they cannot fulfil in the rush and bustle of urban life for any length of time—I am, etc.,

GRACE H. WALKER

### Ménière's Syndrome

SIR—We have been interested in the work done by Mr E. R. Garnett Passe and Dr J. S. Seymour (Nov 16, p. 812) in treating Ménière's syndrome by interrupting the sympathetic fibres from the stellate ganglion running along the vertebral artery, and in some cases by dividing the artery as well. They raised the problem of ligating the second vertebral artery if the condition should also develop on that side, and they suggest that the safety of this procedure should first be proved by animal experiment.

We have been doing some experimental work on blood flow in the circle of Willis using rabbits, of the readily available animals they have a circle most like that of man (cats and dogs are especially unsuitable for anatomical reasons). Ligation of both vertebral arteries has been done by other workers besides ourselves and does not result in death. Using a rapid coagulation technique modified from that of Franklin and Amoroso<sup>1</sup> we have confirmed earlier work that under normal circumstances the vertebral arteries supply the hind-brain and posterior-cerebral artery territory. And we have shown that in this animal carotid and vertebral blood-flows meet and oppose each other without appreciable mixing in the posterior communicating arteries. Any alteration in balance of pressure between the carotid and vertebral circulations causes the posterior communicating artery to function as an anastomosis and blood flows along it.

In man the condition of the posterior communicating arteries, therefore, would appear to be all-important in the main problem under consideration. Normally these are relatively smaller than in the rabbit but they show great variation. Dandy<sup>2</sup> found that they were 'normal' in less than 50% of 1,033 cases, and in 3% of 1,603 cases they were both absent. Freeman and Moran<sup>3</sup> found absent or threadlike posterior communicating arteries in 23% of 200 cases averaging 59 years of age. These cases showed a higher incidence (31.8%) of cerebral infarction than cases without these defects (23%). In view of these variations it would be unwise regardless of results of animal experiment to attempt to predict the results of bilateral vertebral ligation especially in older patients.

Under rarer circumstances the structure of the circle of Willis might render even unilateral vertebral ligation dangerous. To investigate the presence and patency of the posterior communicating artery in any individual radiographic studies of the circle of Willis or else close observation could be made at operation during bilateral vertebral compression.

Another factor is the possibility of thrombosis. The injection of small doses of thrombin into one vertebral artery resulted in death of the animal from respiratory failure followed by cardiac failure.

whereas larger quantities injected into the internal carotid artery did not cause death. While the thrombosis resulting from intravascular injection of thrombin is hardly comparable to that which might follow the ligation of a vessel, we think this observation worthy of record. Although much of this is theoretical as regards man, we feel that the factors mentioned should be appreciated if interference with the vertebral artery, whether by ligation or by injection of radio-opaque substances, is to become more common than hitherto—We are, etc.,

### A Gastric Bezoar

SIR—On Oct. 16 a man aged about 40 was admitted to the Waveney Hospital, Ballymena, he had had vomiting and stomach discomfort for about three weeks. He was of low-grade intelligence, and no clear and reliable history of his condition could be got from him. So far as we could find out he complained of a dull, aching pain in his epigastrium which radiated upwards, occasionally woke him up at night, and was relieved by a drink of milk. There appeared to be no previous history of stomach trouble. His appetite was good, and he had no loss of weight.

On examination by the H.S. when admitted his abdomen was noted as lax and mobile, with no tenderness or rigidity, and no abnormality was discovered. When examined next day by me I noted some abdominal distension and a certain amount of rigidity, making it impossible to palpate the abdominal organs clearly. On Oct. 17 he had a fractional test meal done but there was great difficulty in getting an adequate specimen from the stomach at any time. Such specimens as were got showed no free HCl and diminished total acidity. On Oct. 18 he was x-rayed. On examination six hours after a barium meal the meal seemed to be in the normal position in the caecal region, but there was a faint shadowy picture of an enlarged stomach visible. On getting his second barium meal the stomach was shown considerably enlarged, with some thinning of the barium shadow in the pyloric and cardiac regions which could hardly be described as definite filling defects.

When I examined him on Oct. 21 before a meal he was quite relaxed and I was able to feel a definite mass occupying the whole stomach area and freely movable. At operation on Oct. 22 I removed from inside his stomach a rolled mass of hay and straw weighing 1 lb 12 oz (793 g). This was tightly rolled and matted in the pyloric region and looser and less compact in the cardiac region. His recovery has been uneventful save for a stitch abscess, and his only complaint at present is that he does not get enough to eat—I am, etc.,

Ballymena N. Ireland

J. ARMSTRONG

### Intussusception Due to Carcinoma of Colon

SIR—Surely Mr R. A. C. Owen (Oct. 30, p. 786) is wrong with regard to the rarity of intussusception in adults. Interesting though his cases were, and that the opposite holds true, namely that they are too common to require reporting? If not, my first case, an ileo-ileal intussusception headed by a submucous lipoma is hardly relevant to his article, but my second has its own interest.

The patient was a woman aged 49, and she was seen on July 16, 1940, with a history of increasing constipation. A mass was felt attached to the left corner of the uterus. She was later moved to the Staffordshire General Infirmary, and on July 26 a growth (histologically adenocarcinoma) of the sigmoid colon together with attached portions of the uterus and bladder wall was removed, using a modified Paul operation. She returned home healed and well in September 1940, and nothing further was heard of the patient till March 20 1945. At this time she had a sudden violent attack of abdominal pain and vomiting. This gradually settled down, and a subsequent barium enema gave a "normal" (i.e., indeterminate) result.

It was more than a year later that she was confined to bed with griping pains and constipation (May 7, 1946). She was treated expectantly with oil and magnesia, with fair apparent success. On

May 16 there was a relapse, and a vague tumour in the left upper abdomen appeared together with visible peristalsis. On May 17 blood was passed per rectum, and laparotomy showed the head of an intussusception from the mid transverse colon to have just reached the splenic flexure. Reduction was easy, and a malignant growth was manifest. Search of the abdomen showed no distant secondaries nor any evidence of trouble in the sigmoid colon or pelvis, and the operation was completed by the formation of a caecostomy. On June 7 nine inches of the mid transverse colon was excised centring on what proved again to be an adenocarcinoma, and continuity of the bowel restored by side-to-side anastomosis. The caecostomy shortly closed and the patient returned home on June 25 and has remained well since.

A personal view is that the second carcinoma had a quite distinct origin from the first. The occurrence of pain, etc. fifteen months before its first discovery indicates a possible polypoid origin which might be common to the two but no other polyps were manifest at the 1946 operation. However, the concurrence of to my mind two not very rare conditions, discrete colonic growths with intussusception of one of them is unusual and comment on either subject would be welcomed—I am etc.,

Stafford

G I WILSON

### Aortic Dissecting Aneurysms

SIR—I read with interest the article on aortic dissecting aneurysms by Mr D P van Meurs in your issue (Sept 25 p 599) which reached here this week, just two days after a discussion on the same subject had taken place at the weekly clinico-pathological conference at the Royal Hobart Hospital attended by resident medical staff consultants, and local general practitioners.

The case under discussion was a man aged 65 whom I was called to see at 6 a.m. on Nov 1, 1948. He had been seized with an acute abdominal pain on rising and had collapsed to the floor. On arrival I found him on the floor in a state of severe shock. He was extremely pale, sweating, but not dyspnoeic. He retched twice in my presence, but did not vomit. His radial pulse was of poor volume, rate 96, rhythm regular. The heart was not enlarged clinically, and the sounds were normal. Blood pressure was 80/40. There was rigidity of the abdominal musculature in all areas. I considered he was far too shocked for a case of perforated abdominal viscus and sent him to hospital with a diagnosis of dissecting aneurysm of the abdominal aorta. He revived somewhat after admission to hospital and was able to give more history. He had no relevant past history. The abdominal pain commenced soon after he retired, and it woke him at intervals during the night. He was seen after admission by a surgeon who advised against laparotomy. The patient was then feeling much better and had only a dull ache in the abdomen. The abdomen was rigid all down the right side and out into the right loin. On the day following admission he still had a fair amount of pain. At 2 p.m. he began to sweat, went pale and died in a few minutes.

Post mortem examination showed a rounded aneurysm of the abdominal aorta about 3 inches in diameter situated just proximal to the bifurcation. The aneurysm had ruptured over a wide area anteriorly, and several pints of blood were present in the adjacent tissue spaces and in the mesentery and peritoneal coat of the intestines. The aneurysmal sac was adherent to the lumbar vertebrae, but there was no erosion. The inside lining of the aneurysm showed some calcification, much necrosis and stripping of the walls and some slight tendency to longitudinal wrinkling. The proximal aorta and the iliac arteries were arteriosclerotic, with calcareous plaques. Apparently the aneurysm had been leaking all night, and the effort of rising had caused further dissection with terminal rupture 36 hours later.

I am indebted to Dr J C Laver, superintendent, Royal Hobart Hospital for the clinical notes after admission and to Dr Campbell Duncan, Commonwealth Government pathologist, Hobart, for the post mortem report.

—I am etc.

Hobart, Tasmania

A W O YOUNG

### Bronchial Asthma and Thiopentone

SIR—Dr Brian D L Johnson's letter (Nov 6, p 837) calling attention to the fact that bronchial spasm can follow the administration of pentothal to a patient suffering from bronchitis and asthma would have been more convincing had he described his induction in greater detail. That type of case can be safely anaesthetized with thiopentone provided due

care and attention are given to the underlying pathology. Most or all of the lung tissue is affected by bronchitis emphysema and asthma in varying degree, probably there is bronchiectasis and residual sputum in addition. Secondary deposits are also possible in the type of case described by Dr Johnson. Such a patient is quite unfit for the strain of any athletic performance and she is equally unfit for a rapid induction with drugs that will also cause respiratory depression. Such cases are sick patients and must be anaesthetized with considerable respect. For some years I have adopted the following procedure in all bad risk cases and without exception have always had most satisfactory results.

The patient's arm is put on a splint. A syringe of 20 ml of thiopentone 5% is taken and the needle inserted into a vein. The syringe is strapped on but no injection is made. With some 8 litres per minute of oxygen running through a Boyle's machine a mask is placed near the patient's face. He is told what is happening—that the oxygen is to help his lungs, etc., that he will not go to sleep yet, and that he will be told when he is to be put to sleep. I have never seen any anxiety follow this procedure. While talking to the patient the mask is lowered on to his face, frequently the colour improves, but in any case at the end of about two minutes or less 1 ml. only of thiopentone is injected and the patient is told that he will go to sleep in the next few minutes. Rarely does this dose upset respiration but if it does no further injection must be made until good movement has been restored. Some 30-45 seconds later a further 1 ml is injected and the result observed. The injection can now be continued at an increased speed, but slowing of respiration must not be ignored. After the first 5 minutes, and usually after 0.5 ml thiopentone has been given, the oxygen can be reduced and N<sub>2</sub>O added. The mixture should be 50% at first, and the O<sub>2</sub> content should not drop to say 20% in under 10 minutes, though the operation can have started before then.

Bronchial spasm, if it occurs, will be preceded by a bout of coughing. Further steps that can be taken to avoid this coughing are: (1) Do not risk inserting an artificial airway at too light a plane of anaesthesia. Be sure that an adequate plane has been reached before this is done. (2) If further anaesthetic agents are to be given, remember that ether will set up violent coughing if not used carefully. Chloroform is at its best in this type of case and makes a good stepping stone to ether.

Finally, though one has had a smooth induction and anaesthetic a stormy recovery may follow. Long bouts of coughing and straining can be separated by periods of breath holding. This tends to produce a blue patient, perhaps in spite of the administration of oxygen. My conclusions from this, if a patient has a really chronic chest, are as follows: (1) Use locals if reasonable—e.g., for suprapubic drainage. (2) Limit the thiopentone to 1 g, and a quicker recovery will ensue. (3) Early removal of artificial airways is important. (4) Do not leave the patient lying flat if coughing is occurring. They are better well propped up.

The administration of oxygen before inducing anaesthesia is too little practised. I have twice previously described my technique in the *Journal* and know how smoothly bad risk cases can be induced in this way. It is also very regrettable, but equally true to say that many patients are inadequately oxygenated when they go blue from any cause. This crime—for to me it is none other than culpable negligence—is by no means confined to the junior anaesthetist and may even be committed in teaching hospitals—I am, etc.

Southsea

H B C SANDIFORD

### Pulmonary Rheumatoid Disease

SIR—The paper by Drs Philip Eilman and R E Ball (Nov 6, p 816) raises several interesting points. The first is that, whatever causes pulmonary fibrosis in rheumatoid disease, it is a rare finding in such cases. Skiagrams of the chest are usually normal in this disease. In view of this we feel justified in reporting a case we have at present under our care.

A clerk, aged 43, first developed symptoms of rheumatoid arthritis in 1934 in his feet at first and later in his knees. Under physiotherapy the disease remitted, only to reappear in more active form in 1941 in his hands, wrists, and elbows. A further relapse occurred in 1947 when his shoulders became affected. In 1943 he became aware of the onset of swelling and redness of the finger tips, which subsequently remained swollen and pink. In 1945 he had a short sudden attack of dyspnoea with palpitations. Skiagrams and electrocardiographs were normal. One year later a sharp pain of pleural

type appeared at the right base, abating within a fortnight. Treatment had been gold, vaccines, lactic acid intra-articular injections, and physiotherapy.

His previous history was as follows. In 1928 he was treated for thyrotoxicosis by iodine and deep x ray therapy. The last treatment was given in 1932. The condition subsided and has never relapsed since. Total dental extraction was performed in 1934. He gave no past history of chest trouble and had never been exposed to dust hazards. His family history was irrelevant. An elder brother also had thyrotoxicosis.

On examination he was found to have bilateral exophthalmos, there were no other signs of thyrotoxicosis. His fingers were markedly clubbed, the terminal phalanges being bright pink in colour. The cardiovascular system was normal. B.P. 120/80. The chest was barrel shaped, maximal expansion 2½ in (5.6 cm). A few fine basal rales were present. Signs of advanced rheumatoid arthritis were present in elbows, wrists, hands, knees, and the left shoulder.

The Wassermann reaction and gonococcal fixation tests negative. Blood count normal. Haemoglobin 95%. Electrocardiograph normal. Serum cholesterol 214 mg per 100 ml, plasma proteins 6.4 g per 100 ml (albumin 4.2 g, globulin 2.2 g). ESR (Wintrobe) varied between 13 and 34 mm. Non protein nitrogen 22 mg per 100 ml, plasma uric acid 3.7 mg per 100 ml. Serum alkaline phosphatase 9 units. Thymol turbidity 2 units. Thymol flocculation 1+. Serum colloidal gold negative. Twenty-four hour specimens of urine contained 1.2 g creatinine and 0.2 g creatine.

Biopsy of the skin and deltoid muscle was reported on by Dr A. W. Morgan as follows: "The capillaries of the cutis vera are rendered prominent by congestion and endothelial swelling, also by a mild lymphocytic infiltration of the perivascular lymph spaces. The portion of muscle shows little of note in the fibres themselves and no fibrosis. There is, however, a focal infiltration of round cells between the fibres and a slight degree of sarcolemmal nuclear proliferation."

Skilagrams showed typical rheumatoid changes in knees, hands, and wrists. The cardiac outline was normal. The lungs showed a fine reticulation in lower and middle zones, with coarser nodulation in the outer quadrants of the middle zones. Progress was slow but encouraging. The patient is still under observation as an out-patient after spending four months in the ward.

The case is still *sub judice* but we consider it worth reporting in the light of Ellman and Ball's report. The history and clinical and radiological findings do not suggest pulmonary tuberculosis or bronchiectasis. Polyarteritis and scleroderma were considered as diagnoses but were rejected. We have for some time considered him to be rheumatoid disease of the lung, as the pulmonary changes appeared during the course of the disease were not accompanied by symptoms, and did not appear due to other causes. The patient an intelligent man is certain that finger clubbing appeared first in 1943 between two acute relapses in the rheumatoid condition. In view of Ellman and Ball's report we feel inclined to adhere to our diagnosis and advance this, tentatively, as a further report of pulmonary rheumatoid disease. —I am, etc.

London S.W. 1

F. DUDLEY HART

### Hereditary Haemorrhagic Telangiectasia

SIR—I was most interested in the article written by Dr C. P. Petch (Oct. 30, p. 785) on this condition sometimes known as Osler-Weber disease (Parkes-Weber first stressed hereditary nature by describing a family in 1907 and he reviewed the literature in 1924). In reviewing some of the literature (with a report of a rather unusual case with a four-generation pedigree) in the *Journal* of March 31, 1945 (p. 440) I was impressed that the disease was not quite as rare as the number of actually recorded cases might indicate. Like Hurst and Plummer stated this, and Price goes so far as to say that the condition may be as common as haemophilia. Certainly the difficulty has been to distinguish clearly the condition from disorders like purpura haemophilioid, polycythaemia, and so on.

The condition could perhaps be enumerated as follows: (1) the presence of a Mendelian dominant and not recessive mode of inheritance; (2) the presence of telangiectases; (3) the tendency to haemorrhage; and (4) the multiplicity of lesions. The condition is a fairly benign course, the most Mendelian form of the disease possibly the one would specialize itself in a particular organ, as was borne out by Campbell, who did some work on the condition. The telangiectases may be present on the skin, the mucosa of the alimentary canal, the bronchial tree or even in the capillaries of the brain,

but usually they are found in the nose. The bleeding is sporadic, epistaxis being the common feature. Hess's test is negative. It is this fact which would throw doubt on the cases reported by Singer and Wolfson<sup>1</sup> in 1944.

Finally, I would like to mention that I was not quite certain at what stage the patient reported by Dr Petch had attempts at cautery done. Hurst and Plummer<sup>2</sup> described a method of immediate control by the inflated-finger-stall device, when the bleeding settled cauterization of the larger naevi was performed. This has been found a most efficient method of treatment, though admittedly a new crop of naevi are liable to occur—I am, etc.

### H 11 in Malignant Disease

SIR,—Case 5 reported by Mr J. H. Thompson and Dr G. J. W. Ollerenshaw (*Journal*, Nov. 6, p. 835) and the third case referred to by Dr H. Josephs (Nov. 13, p. 876) appear to be identical with a case recently under my care. In both the above references the assumption is made that here was a case of carcinoma of the rectum with secondaries in the liver which disappeared as a result of H 11 therapy. Every doctor who accepts this assumption will feel that a very good case has been made out for this therapy in cancer. The history of the case known to me, however, is that the nodules in the liver were not typical secondary carcinomatous nodules. They were described by the original operator as "very small nodules," and in a personal communication he tells me that "he would not now regard such nodules as cancerous." Every surgeon of experience must have met similar small nodules which on section turned out to be fibromas or hepatomas or small cysts or other benign lesions. The patient has done very well, and I do not deny that H 11 may have been beneficial, but it has not been proved that such a striking and unusual effect as the disappearance of liver secondaries has occurred.—I am, etc.

FAUSET WELSH

### Pensions for Diabetics

SIR,—I am rather surprised at the somewhat unsympathetic attitude adopted by Dr R. D. Lawrence (Nov. 13, p. 875) in view of his well-known interest in the welfare of the diabetic and of his work for so many years for those who have this handicap. As he points out, recruits found to have glycosuria were most carefully excluded from service with the Forces unless this condition was proved to be of the harmless variety. It was therefore to be expected that the incidence of diabetes among serving members of the Forces would be low. But nevertheless many were admitted with a diabetic heredity, in these exigencies of war might easily precipitate a diabetic state which might never otherwise have occurred, or antedate its onset.

A case of this type came under my own notice. This man, whose mother died of diabetes, was passed fit for service, trained for the commandos, put in strenuous service in Syria, Tobruk, and Burma, contracted septic infections, epidemic jaundice, dysentery, scrub typhus, and malaria, and fell a victim to diabetes. In establishing a claim for pension it was not a question of war conditions only but war conditions plus repeated infections to which this man would not have been otherwise subjected and which were likely to antedate the onset of diabetes in a predisposed individual.

Where the onset of diabetic symptoms follows immediately upon an incident under Service conditions—e.g., a head injury in a motor-cycle accident or on immersion in the icy North Sea—both examples of actual cases—no one can maintain that the accident had nothing to do with the onset of diabetes. In fact any unprejudiced observer, be he medical, scientific, or lay, would take the view that cause and effect might reasonably be associated here. Furthermore, as I understand the position it is not for the claimant to prove cause and effect without the shadow of a doubt but for the Ministry to show without any doubt that the incident and the onset of diabetes could not have been in any way associated. I should therefore still

make the plea that where there is any possibility that diabetes occurred as a result of accidents or strain during service the case of the claimant should get a fair and full hearing.

I cannot agree with Dr Lawrence that diabetes is in every instance a disease which can be so lightly regarded that it will not produce disability and some incapacity in earning a living. The severe diabetic is liable to sepsis following minor injuries and abrasions and to major effects from minor infections. He may be unsafe in occupations involving proximity to dangerous machinery and in particular he may easily fall a victim to tuberculosis. I have already seen this occur in a diabetic pensioner. In conclusion, I still feel very strongly that the diabetic is worthy of his pension—I am, etc.

Aberdeen

A LYALL

### Bornholm Disease

SIR—Dr A F T Ord's admirable description (Nov 20, p 916) of his cases comes close to Daa's original description of the syndrome (as quoted by Sylvest<sup>1</sup>) which he named epidemic myalgia. As a rule the patient has a stitch in one side of the chest, which is often accompanied by pains in the back, shoulders, epigastrium, and abdomen. Several outbreaks of epidemic myalgia have been described in the literature,<sup>2</sup> and most observers agree that there are no x-ray changes demonstrable in the disease. In this connexion it is interesting to note that if the film was correctly interpreted some mid zone opacity was seen in Dr Ord's first patient's chest thus bringing atypical pneumonia into the differential diagnosis.

The other syndrome which ought to be considered in the differential diagnosis is the non glandular form of infectious mononucleosis. In a recent paper<sup>3</sup> I have described the extremely difficult differential diagnosis between the atypical forms of infective mononucleosis, epidemic myalgia, and the pre-paralytic stage of acute poliomyelitis—an important point in times of an epidemic.

I cannot but concur with Dr Ord's criticism of the indiscriminate use of the 'sulpha' preparations and penicillin in these cases. Some yet unpublished therapeutic response has been demonstrated in at least infectious mononucleosis with para-aminobenzoic acid (PABA). It is possible that the drug may be effective also in the more uncommon epidemic myalgia, and it is obvious that to give these patients sulphonamides is just the wrong thing to do.

The differential diagnosis can be made easier if white counts are taken of these patients, a procedure certainly easy for a hospital and accessible even to a general clinician. In a case of frank pneumonia warranting chemotherapy or penicillin one would expect marked leucocytosis with increased polymorphonuclears, except in a very few toxic cases of bone marrow depression. The white counts in epidemic myalgia are either normal or only very slightly increased, and in infectious mononucleosis the diagnosis can be safely made by demonstrating the typical young mononuclears ('atypical lymphocytes' of American writers). As a matter of fact the differential white count is the only safe way of diagnosis for the latter syndrome since the Paul-Bunnell reaction is positive only in less than 50% of the cases during the first fortnight and cannot be demonstrated at all in almost 30% of the cases.<sup>4</sup>

To sum it up a little more clinical observation, like that demonstrated by Dr Ord and much less mechanized medicine, and the list of rare and uncommon diseases will have to be radically revised—I am, etc.

### Out-patient Electric Convulsion Treatment

SIR—Dr J F Cooper's letter (Nov 13 p 878) prompts me to report that at the Middlewood out-patient clinic ECT has been used regularly since 1941 with results very similar to those recorded in Sir W P Mallinson's article (Oct 2 p 641). We can confirm the safety of this form of treatment when carried out by experienced psychiatrists with facilities for the immediate admission of the patient when desirable. In over 3,000 treat-

ments no complications, fractures or untoward incidents have occurred. No restraint has been used apart from a loose draw sheet passed around the trunk and arms. Oxygen has never been used and complaints of post-convulsive headache have been few and hardly worth mentioning. Three nurses are utilized, mainly for the purpose of transport of patient to the recovery rooms and subsequent supervision.

Fear of treatment is a noticeable feature in a minority of patients and probably the majority would confess to some apprehension if asked about it, but the benefit derived from treatment far outweighs these misgivings. The number of treatments given in one course seldom exceeded eight, and I can recall only one or two patients in each year who gave up attending through fear. For the latter patients and for those who experience a post-convulsive period of excitement Dr Cooper's recommendation of premedication with small doses of pentothal is of value but I doubt the wisdom of complicating the procedure by routine intravenous injections—I am, etc.

### Clouding of Surgeons' Spectacles

SIR,—Like most surgeons who wear glasses, and particularly those who prefer a mask with a cellophane layer, I have tried many methods of preventing steaming. Until we get our 'green forms' for the special glasses recently described, may I recommend the following simple method which was evolved under the testing conditions of a hospital where the atmosphere was particularly humid as well as very hot?

A thin piece of soft cotton-wool about 5" x 2" is partly torn across the middle to give it a butterfly shape, the 'butter fly' so formed is placed along the upper edge of the mask before it is assumed. It causes no irritation, and experiment soon determines the smallest amount of wool which will prevent one's breath from passing between the mask and the nose. Unlike special preparations for the glass, which soon lose their effect, the wool enables one to pass the longest, hottest mornings operating with unclouded glasses—I am, etc.

### Psychiatry

SIR,—Whilst I am grateful to your critic, Dr Eliot Slater (Nov 20, p 906), for reviewing my book on psychiatry, I feel, nevertheless, obliged to register a mild protest against some of his remarks. A book which sets out to deal with the whole of the subject of psychiatry in some 380 pages cannot, surely, afford to be 'full of asides'. The latter were intended to be not off-stage whispers but positive and fully thought out statements and reflections, whose extra-textual quotation can only be calculated to distort their meaning.

The impression given by Dr Slater that the book emphasizes body-mind dualism overmuch must, I fear, be imputed to his reading of it, not to my writing. Indeed, the theory embodied in the book is in effect a mind-body monism—if I may so put it. It purports, furthermore, to treat psychiatry as if it were concerned with mental illness, with psychic deviations from an accepted norm. If in championing this viewpoint I have run counter to the, at present, more fashionable notion of looking at the subject from a physical angle, it is regrettable that I should be chastised for it.

Dr Slater quotes me as saying, or rather meaning that 'pre-clinical disease is an unconscious process'. Yes indeed it is. A conglomerate of carcinomatous cells, for instance, may lead its parasitic existence for quite a time to the complete unawareness of its host—would that it were otherwise! But I went much further than this. I meant to convey the assumption that unconscious dynamic processes and physical disease might well stand towards each other in the relationship of cause and effect or at the very least as concomitants in one single and indivisible process.

I am well acquainted with Dr Eliot Slater's learned work or genetics as well as with his orientation in psychiatry and I have met him on several occasions. May I end by thanking him for not sparing the rod, and for wielding it with more grace and charm than is usual among psychiatric opponents?—I am, etc.

## "Dye"

SIP.—I note a regrettable tendency on the part of radiologists and other clinicians to refer to many contrast media used in radiology as 'the dye'. The *OED* gives the following meanings of the noun: (1) colour produced by dyeing, and (2) material used for dyeing.

Is it really necessary to be so slipshod in the use of our native tongue, even for the sake of brevity? The fact that tetraphenolphthalein is, until acidified, a blue dye is no justification for so describing such colourless substances as phenodol, iodoxyl diiodone, thorotrast, and iodized oil. If this goes on we shall soon be giving barium dye to show a duodenal ulcer. I write in the hope that this habit will soon be a natural death—I am, etc

## Eye Bank Needed

SIP.—I am an Australian and have just returned to London after several months of study in the USA. I feel there is a very real need in England for the establishment of an eye bank. The American eye bank is very busy and functioning splendidly. It has enabled thousands of corneal grafts to be done which have undoubtedly restored vision to many blind people. It receives as much support from the American people as the blood bank. In a small country like Britain an eye bank should be very easy to organize—I am, etc

## Marxist Genetics

SIP.—Dr C D Darlington's sarcasm at the expense of *Soviet Biology* (Nov 13, p 862) might have been more effective if it had been more accurate. A particular example of this inaccuracy is his reference to "the idealistic metaphysical bodies the chromosomes," implying that this is Lysenko's attitude. In fact Lysenko states: "We recognize the chromosomes we do not deny their presence. Is heredity transmitted through the chromosomes in the sexual process?" Of course it is (p 43). Again Dr Darlington remarks on the alleged deletion from Lysenko's report of any reference to his views concerning the competition of members of the same species. Yet if only Dr Darlington had read as far as p 38 he would have seen an explicit reference to this very theory.

Dr Darlington also refers to what he terms "a new figure in Soviet mythology" and adds, "We shall all watch Williams with him well in his watching, for Williams died 20 years ago." He was a very well known Russian soil biologist whose ancestors emigrated there. A review containing such inaccuracies cannot be taken seriously. Dr Darlington appears to have been chiefly motivated by reasons other than scientific. Lysenko's report however is well worth serious study to all who are genuinely interested in genetics. He is by no means an unscientific farmer but a scientist well conversant with the current theories of formal genetics—I am, etc.

BARBARA MCPHERSON

## Safer Milk

SIP.—In the annotation entitled "Safer Milk to Come" (Nov 13, p 868) you say: "About one quarter of the milk supplied to schools is neither from a TT herd nor has it been tested." This is incorrect. Figures for school milk at the beginning of this year were:

From TT herds	92%
Not tested	~6%
	98%
From TT herds	~22%
Not tested	~6%
	98%

It is worth noting that still receive a daily ration of milk are not tested in the Welsh mountains where no TT milk is available. The fact that the milk is kept in a cold storage tank is no guarantee of safety.

W A LITTLE

## POINTS FROM LETTERS

## Breast feeding

Dr CHARLES A MARSH (Bath) writes: Another cause of the failure of lactation is the abolition of the free movement of the baby's arms. In normal lactation the baby's hands gently massage the mother's breast, and this is a most important factor in the flow of milk. The modern plan of wrapping the baby up so completely that the arms are invisible and useless, thus turning it into a mummy, is altogether contrary to nature and limits the co-operation between mother and baby so well described by Dr Rachel Pinney (Nov 13, p 878) as a love act. A calf or a lamb constantly varies suction with bumping its head against its mother's udder, massage by the baby's hands is just as natural though less violent. The only reason I have been given for wrapping the arms is to prevent the baby scratching its face, involving possible criticism of the nurse, but this can be met by cutting the baby's nails. The fact that there is little difference in the amount of breast-feeding in hospital or at home does not affect this question, as the district midwives get the same training. The old fashioned tight binder has gone out and the new fashioned mummification come in. I do not know which of the two is worse.

Dr C T NORRIS (London, SW 6) writes: With experience similar to Dr James S Hall (Nov 20, p 919) I have only found one mother among all those who really want to feed their babies who could not do so when afforded adequate supplies of calcium and iron, which I now use in the form of calcium lactate gr 10 or 15 (0.65-1 g) in 2 dr (7 ml) of the *N.W.F. mistura ferri et ammonii citratis*, tds. The criterion is not quantity only, a thin watery milk, however plentiful, requires this treatment, and so does a mother, whatever the lactal condition, who resumes the puerperal flow on returning home or who menstruates during lactation. These facts are not and cannot be known to those who lose sight of the mother 10 or 14 days after delivery, in whose hands most of the midwifery now lies, and who consistently fail to induce the mother to see her own doctor for further advice when they send her out of their care. They also do harm by sometimes advising 3-hourly feeds, against which no mammary organization I have met can contend indefinitely. In at least half the cases where the baby is presented as the patient for a vague asthenia or wind, treatment is needed on these lines for, and through, the mother.

## Carcinoma of Cervix

Dr E MALCOLM CLARK (Fort Hall, Kenya) writes: Mr Sampson Handley has stated (Dec 20, 1947, p 1010) that the relative freedom of Jewish women from carcinoma of the cervix was almost certainly due to circumcision of Jewish males. He also quotes the case of circumcised Fijians, and even goes so far as to state that as a consequence of present standards not being as far ahead as the hygiene code of Moses thousands of women are annually sacrificed to this form of cancer. Amongst the Kikuyu tribe in Kenya all the males are without exception circumcised before puberty. Carcinoma of the cervix amongst the females of the tribe is, however, so far from being rare, the commonest of all forms of cancer. In a series of 82 consecutive cases of cancer amongst the Kikuyu (both sexes) I found no less than 12 cases of carcinoma of the cervix. With one exception the diagnosis was confirmed by histological examination at the Medical Research Laboratory, Nairobi. One case not so confirmed was operated on by a very experienced gynaecologist in Nairobi. It was found that owing to the advanced state of the growth it was impossible to perform a hysterectomy, there could be no possible doubt as to the diagnosis. It would not, I think, be justifiable to attribute the low incidence of carcinoma in Jewish and Fijian women to circumcision in their men folk. Rather would it not be safer to suggest some racial factor which we do not as yet fully understand?

## Another Unusual Case of Twins

Dr J K POMEROY (Lemberg, Canada) writes: With reference to the memorandum on an unusual case of twins by Drs J H Young and F E Cull (Oct 16, p 713) I was called to a maternity case thirty miles away on April 5, 1948. When I arrived the woman was in labour. I diagnosed twins. I had not been in the house many minutes when I delivered the first foetus, a girl, by the breech and divided the cord. The next presenting object was a placenta. At this point the cord was two cords leading into the uterus and at the external end of one a placenta was attached. Then came the second foetus, a boy, vertex presenting. As I had not severed the cord there I was with the second foetus connected by an intact cord with its placenta—the placenta that had already been expressed. The placenta belonging to the first foetus was expressed in a few minutes. The woman made an uneventful recovery. I do not know the woman's history as I saw her only the once. I do know she was a part with the first child about 4 years of age. It is a rare condition. The sequence was the same as Young and Cull's, foetus A placenta B foetus B, placenta A.

## Obituary

### STUART McDONALD, M.D., F.R.C.P.E.D.

Many of those who were students in medicine at Newcastle upon-Tyne before the last war and many of the older members of the Pathological Society will learn with regret of the death on Nov. 15 of Stuart McDonald, emeritus professor of pathology in the University of Durham.

Stuart McDonald was born at Castle Douglas and educated at Dumfries Academy going on to the University of Edinburgh where he graduated M.B., C.M. in 1896. In 1907 he proceeded M.D., obtaining a gold medal for his thesis on subacute necrosis of the liver, a subject of which much less was known then than is the case to-day. Shortly after qualifying he began to specialize in pathology, spending some time at Freiburg, where he learnt much from the teaching of Aschoff. Then for some years he lectured on his specialty in the extramural school at Edinburgh. In 1909 McDonald was appointed to the chair of pathology in the University of Durham, and there he remained for the next twenty-eight years, till his retirement in 1937. He published little in his later years with the exception of an important study on asbestosis in 1927, but he was a constant attendant and a well-known figure at the bi-annual meetings of the Pathological Society. He threw himself with zest into the life of the University, becoming dean of the medical faculty and an officer in the Medical Detachment of the Officers Training Corps as well as taking a keen and active part in many student activities. He was also deeply interested in forensic medicine and became known throughout the North of England as a reliable expert witness. Professor McDonald was for long a member of the Newcastle upon-Tyne and Northern Counties Medical Society and eventually became its president. His services were much in request as an external examiner in pathology in many universities in England and Scotland, and in addition he served both as secretary and as vice-president of the section of pathology at B.M.A. Annual Meetings.

Despite his love of cities McDonald was essentially a countryman who looked forward with zest to the days that he could snatch beside his beloved trout streams. His years of retirement were spent among the quiet Peeblesshire hills, where he could indulge to the full his taste for rural things. His life at the end was saddened by the death in 1946 of his son, who was professor of pathology in the University of St. Andrews.

### J. B. SIMPSON, C.B.E., M.D., F.R.C.P.E.D.

Dr. James Bertie Simpson, of Golspie, died on Nov. 16 in Edinburgh at the age of 85. Dr. Simpson was a student at Edinburgh University, and graduated M.B., C.M. in 1887, proceeding M.D. in 1892 after a period of study at Leipzig and Vienna. He was elected F.R.C.P.E.D. in 1925, and was a deputy-lieutenant for the county of Sutherland. He was awarded the O.B.E. in 1920 and was made C.B.E. in 1942. Dr. Simpson was an assistant in Ballachulish, Argyle, before settling in Golspie. He was chairman of the Caithness and Sutherland Division in 1922-3 and again in 1941. He had been a member of the Highlands and Islands Consultative Council and of the Insurance Acts Subcommittee for Scotland. He was an active member of the Scottish Committee from 1933-40 and again in 1945-6. He was also a representative at Annual Representative Meetings on several occasions.

Dr. D. W. D. MacLaren writes: "With the passing of Dr. J. B. Simpson our profession in the North of Scotland mourns the loss of its most honoured and distinguished representative."

"Simpson of Golspie" was indeed a household word in all our northern counties. His devoted work over many years on behalf of his medical colleagues can never be forgotten. He was a keen and enthusiastic 'B.M.A. man' holding the highest positions in his Division and Branch, and for years the trusted delegate to its national councils and committees in Edinburgh. His dynamic and colourful personality found its scope in so many local and county activities that it was always a source of amazement how he found time for them all. In addition he ran a large and most successful general practice and was

medical superintendent of the county hospital at Golspie. He had the highest ideals and principles and he was always a wise guide and friend to all who sought his advice. With his natural gifts of mind and heart he brought exceptional skill and competence to his professional work in Sutherland, that county which he served so well and which he loved so much. We shall always recall the energetic figure, the fresh complexion, the twinkling eye, the ready wit—caustic at times, but never vindictive—and the abounding humour, wise judgment, and shrewd Scottish common sense of this remarkable doctor, sportsman, and friend. To his son Mr. B. Soutar Simpson, consulting surgeon to the county of Sutherland who continues the family tradition and to all those near and dear to him we offer heartfelt sympathy.

Dr. R. W. Craig writes: "With a cultured mind and a capacity for shrewd judgment Dr. J. B. Simpson combined a rich sense of humour and a strong appreciation of the finer things of life. Straight as a die, he could not tolerate humbug in any shape or form. His penetrating eye, despite its twinkle, could exert an influence which was frequently both chastening and astonishing. As a raconteur he was inimitable, and to spend an evening in Simpson's company was a most refreshing and delightful experience. To the British Medical Association he gave ungrudging and loyal service, but it was only natural that his chief interest should lie in the work of the Highlands and Islands Sub-committee, of which he was chairman for many years. It was in large measure due to his influence that the Highlands and Islands Medical Service achieved its world wide reputation. In the home of the crofter or the laird he was equally beloved and respected. He was a keen angler and an expert deerstalker. He kept himself fully abreast of the latest developments in medical science, and this is reflected in the fact that the late Sir John Fraser was glad on occasion to give his class of clinical surgery the opportunity of having a lecture from Dr. Simpson. A fine example of the best type of family doctor, his character and work will remain an inspiration to all who had the privilege of knowing him."

Dr. GEORGE JAMES IRVINE LINKLATER, chief executive school medical officer to Edinburgh Corporation, died in the City Hospital in Edinburgh on Nov. 24 at the age of 57 after an illness of some months duration. Dr. Linklater had been in the service of the Edinburgh Corporation for twenty-six years. He graduated at Edinburgh in 1912 and proceeded M.D. in 1920. Over the next two years he took the M.R.C.P.E.D. and the diplomas in public health and in tropical medicine. Dr. Linklater was a keen Territorial and served in the R.A.M.C. in both world wars. He received the O.B.E. for his services in the 1914-18 war, and in the recent war he held the rank of colonel, for his services to the Red Cross he was awarded the Order of St. John. He had also been for many years a High Constable of Holyroodhouse. Before his appointment as school medical officer in 1930 Dr. Linklater had been a resident physician in the City Fever Hospital and in the Royal Victoria Hospital, and from there he went on to become a tuberculosis officer in the city. With Dr. John Guy, a former medical officer of health, he was the joint author of a book, *Hygiene for Nurses* which has been the standby of many nurses for years. Dr. Linklater was one of Edinburgh's ablest administrators, and the present high standard of the school medical service is due to his unceasing work. He was at his best with children, as those who saw him hold the rapt attention of large audiences at the junior cinema clubs on Saturday mornings would know. He was an able and lucid lecturer and took a leading part in teaching hygiene to nurses and health visitors. A delightful raconteur and a good companion, he will be sorely missed by a wide circle of friends.—W. G. C.

Dr. L. Carlyle Lyon writes: "It is with profound regret that I, one of his grateful Aberdeen students in the years 1922 to 1927, learned of the death of Professor Theodore Shennan (Journal Nov. 6, p. 839). His value as a teacher was due in part to the unusual personal interest he showed in each one of the students in his class, even to the point of obtaining their individual photographs. His friendliness created enthusiasm for his subject and transformed hard work into a human relationship. He was invariably at his best in the post-mortem room and his textbook remains, in my opinion, a fitting record of his thorough mastery of his subject. All those who studied under him will feel a very personal loss."

## Medical Notes in Parliament

### Sanitary Conditions in the Catering Trade

Mr EDWARD DAVIES on Nov 18 drew attention to the use of cracked and chipped crockery, particularly in catering establishments, and the relation of this use to the spread of infection and disease. Dr BARNETT STROSS said that from what little bacteriological work had been carried out it appeared that reasonable cleansing of an unbroken service with boiled water would leave only a few organisms, whereas on cracked crockery there could be found many types of organism, particularly haemolytic streptococci. Medical students used to hear terrifying stories about diseases which could infect the lips from the use of dirty cups by infected people. They now knew that this happened very rarely, but trench mouth had been prevalent during the war and there was some cause for thinking that it could arise from cracks in pottery.

Dr EDITH SUMMERSKILL said that the Medical Research Council had experimented on china in various stages of dilapidation and the viable bacterial count on the mouth area of a cup was found to vary from a few organisms to many thousands. The number of these organisms was not determined by the cracks or chips but by lack of cleanliness. The Ministry of Health had no record of any serious illness that had been traced to the use of cracked crockery. Apart from sore throats which could be attributed to streptococci there was no trace of any other outbreak. Though germs might be left in cracks after the use of boiling water, there must be a heavy dose of virulent streptococci before anyone could be infected. Cases of food poisoning which had been reported all over the country were not attributable to infected cups, spoons or forks but to food in which organisms had multiplied rapidly. It was quite impossible for organisms to multiply rapidly in cracked cups. Whatever the material used to make utensils, the only safeguard was to ensure that they were properly cleaned. In restaurants throughout the country these utensils were rinsed in water which teemed with bacteria and were wiped with cloths containing many thousands of living bacteria to the square inch. The Ministry of Health was trying to educate the public on the need for a better service. She thought it would be possible for the large catering establishments to give a preliminary wash in a first sink of water containing a detergent at a temperature of 110 to 115° F (43.3–46.1° C) followed by a rinse in a second sink of water at a temperature of about 175° F (79.4° C) for at least thirty seconds, the articles then being allowed to drain dry without wiping. That was much better than wiping them with a filthy cloth covered with bacteria. Crockery, so treated though not sterile, would have a low bacterial count.

Dr Summerskill reminded the House that at present any individual could inform upon the manager of a catering establishment who conducted it in a dirty fashion. He could inform the local authority for an inspector to inspect the establishment. The Ministry felt so seriously about this matter that it was setting up a catering trade working party with the following terms of reference: To make recommendations to the Ministers of Food and Health and the Secretary of State for Scotland as to the precautions considered practicable and desirable with a view to securing the observance of sanitary conditions in the catering trade.

The chairman of this working party would be Sir William Campbell, an authority on food hygiene. It also included a representative of the Ministry of Health, a sanitary inspector, Dr Sutherland, a representative of the Central Council for Health Education, medical and nursing officers from the health departments at the Ministry of Food and persons drawn from different sections of the catering trade. This working party would hold its first meeting on Nov 26. Dr Summerskill added that supplies of crockery were now taking more than 10% of the value of the home market. It was essential, however, to make a national provision prohibiting the use of cracked crockery.

### Civil Defence Medical Arrangements

Mr EDWARD DAVIES on Nov 22 drew attention to the Second Civil Defence Bill. Mr. A. BEVAN said it was a very important Bill. It was a Bill which would enable the Government to make arrangements for the medical service in the event of a war. There had not been any serious consideration of the medical service in the event of a war since the war of 1914-18. It was now only

necessary for the Minister of Health to ask regional hospital boards to identify sites and buildings where they could expand hospital services in an emergency. The same thing was true of blood banks. Blood transfusion services were nationally organized and nationally administered. The same was also true of the ambulance services now the responsibility of the counties and county boroughs and capable of being expanded at any time. So the Government by its wisdom in constructing the National Health Service had at the same time provided the foundations for an effective defence organization.

### Tuberculous Ex-Servicemen in Switzerland

Mr CHETWYND on Nov 23 asked whether the Minister of Pensions had any statement to make on the results of the scheme initiated by the Don Suisse for the treatment in Switzerland of ex-Servicemen disabled by tuberculosis.

Mr H. A. MARQUAND said he would circulate in the official report a short account of the scheme under which, through the generosity of the Don Suisse organization, 180 British ex-Servicemen suffering from pulmonary tuberculosis were provided with free sanatorium treatment in Switzerland. He added that he had conveyed to the Swiss Minister the cordial thanks of His Majesty's Government for the generous and friendly gesture of the Swiss people.

The account which Mr Marquand supplied indicated that in 1946 the Don Suisse offered to provide, for one year, 100 beds in sanatoria at Leysin, in Switzerland, for the free accommodation and treatment of British ex-Servicemen suffering from pulmonary tuberculosis. It was arranged that the patients should be selected by the Ministry of Pensions according to clinical criteria agreed with the Swiss doctors. Medical officers of local health authorities were consulted and patients were selected as follows: from Service hospitals 28, from local authority sanatoria English counties and county boroughs 87, London County Council 34, Scotland 21, and Wales 10. The first hundred patients went to Switzerland in January-February 1947, in six parties. In August, 1947, 76 patients returned on completion of the agreed period of treatment and 79 others went out. Seven patients returned in December, 1947, and 37 in April 1948. The remainder came back in small groups each month up to Aug 31 on which day the scheme ended, having been extended by eight months through the generosity of Don Suisse.

### Basic Salary

Dr SEGAL asked on Nov 25 by what authority local executive councils were empowered to ask a doctor applying for payment of basic salary to submit details of his income from all sources. He demanded an assurance that a doctor who refused to divulge these details would be in no way prejudiced when his claim for a basic salary came up for consideration.

Mr BEVAN said his view was that it was only the doctor's professional income which should be taken into account in such cases.

Dr SEGAL asked whether it would be advisable to investigate incomes at the other end of the scale where overworked doctors might have lists of patients with which they could not cope and might be receiving incomes larger than they ever had before.

Mr BEVAN said that was entirely another question. That matter was being reviewed by the Medical Practices Committee. Until the Ministry had received a survey of the whole country it would not be able to identify those parts where the lists were too large and the areas under-doctored.

Mr RANKIN said that doctors who applied for the basic salary were told that that salary, if paid, was a charge on their colleagues in the area in which they practised.

Mr BEVAN replied that it was true that the £300 a year came out of the general capitation pool as indeed it ought to do because it formed part of a doctor's remuneration. Where however an individual doctor was aggrieved he had the right of appeal to the Minister. Many had so appealed, and decisions had been given.

### Distribution of Doctors

Mr BOSCOM asked how many more doctors were required to enable the service promised under the New National Health Scheme to be given satisfactorily, and what special efforts were being made to train doctors to supply this need.

Mr BEVAN said distribution was as important as total numbers. The Medical Practices Committee was obtaining reports from all areas in England and Wales as at Dec 31 and would then be able to assess where the main under-doctored areas were. The medical schools were already filled to capacity.

Mr BOSCOM asserted that there was a shortage of about 20% of the doctors required.

Mr BEVAN said this was quite incorrect. He added that until the Medical Practices Committee reported he was not in

a position to say what areas were under-doctored. He had no information that the medical profession itself said that approximately 20% were required. It was, however, a fact, he said, that doctors in particular areas were not anxious to say their areas were under-doctored.

Mrs MANNING asked Mr Bevan to consult Sir Stafford Cripps about expanding the medical schools at a very early date.

Mr BEVAN answered that these schools were filled to capacity. It was impossible to expand them beyond the capacity of teachers available to teach in them. The medical teaching staffs formed the limitation.

Colonel STODDART SCOTT asked whether Mr Bevan was prepared to carry out the recommendation of the Goodenough Committee to start another medical school.

Mr BEVAN replied that many recommendations of the Goodenough Committee were already in operation, but it was useless to open medical schools if they did not have staff for them.

#### Prescribing for School children

Mr YORK on Nov 25 asked whether Mr Bevan would provide for the supply, free of charge, of medicines and drugs prescribed by school medical officers at school clinics.

Mr BEVAN answered that medicines supplied at a school clinic would be supplied without charge. If the school medical officer thought a pupil required other medicines he could refer the patient to his National Health Service doctor who could prescribe for free supply under the Service.

**Medical Practices Committee**—Mr BEVAN informed Sir Henry Morris Jones on Nov 15 that up to that date he had received no recommendations from the Central Medical Practices Committee on the question of maldistribution of practitioners. That Committee would obtain by Dec 31 comprehensive reports on the adequacy of the medical services throughout England and Wales. In the light of these reports he would carefully consider any recommendations which the Committee saw fit to make to him.

**BCG**—On Nov 18 Mr WARREY asked the Minister of Health what arrangements were being made for a trial of BCG vaccine in this country, with a view to better protection of nurses, doctors, and other contacts? Mr BEVAN answered that arrangements were nearing completion. He was not yet in a position to make any useful public statement on them but would do so as soon as possible.

**Hospital Charges**—Mr PETER FREEMAN asked Mr Bevan on Nov 18 what charges, and under what conditions, hospitals controlled by his department could impose on patients and whether they were informed on admission of such charges. Mr BEVAN replied that patients could go into pay beds at full cost. Otherwise they could only be charged for extra privacy in single rooms or small wards for the extra cost of certain expensive appliances, and for renewal of appliances damaged through negligence. They were so informed on admission.

**Venereal Diseases**—The National Health Service (Venereal Diseases) Regulations 1948, were presented to Parliament on Nov 22.

**Milk for Old People**—Dr SUMMERSKILL said on Nov 22 that milk supplies were not yet sufficient to allow extra milk to old people. There were 3,000,000 persons in the United Kingdom above the age of 70 years.

**Equal Pay for Women**—Mr BEVAN announced on Nov 25 that the differences in the scales of pay between men and women administrative officers in the National Health Service were being abolished.

**X-ray Equipment**—Hospitals in the National Health Service have received 179 diagnostic x-ray units under the arrangements for central provision. Some types can now be supplied from stock. All hospitals have been asked to state their needs.

**Waiting List**—Persons suffering from tuberculosis who awaited admission to hospital on June 30 1948, numbered 9,208.

**Jamaica**—Of the total births registered in Jamaica in 1946 67.71% were illegitimate. There are at present 5,876 free hospital beds in Jamaica to meet an estimated need of 7,850.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

Professor James C. Spence will deliver the Finlayson Memorial Lecture in the Hall of the Faculty (242 St Vincent Street, Glasgow) on Wednesday Dec 8 at 5 p.m. His subject is 'Poliomyelitis'. Medical practitioners are invited to attend the lecture.

## Medical News

### International Congress of Ophthalmology

Their Majesties the King and Queen have been graciously pleased to grant their patronage to the sixteenth International Congress of Ophthalmology, which will be held in London under the presidency of Sir Stewart Duke-Elder from July 17 to 21, 1950. Any qualified medical practitioner may become a member of the Congress, others not so qualified who have rendered service to ophthalmology and who are approved by the Council will be eligible to attend. Relatives and friends of members will be welcomed as associate members and may attend the opening and closing ceremonies and all social functions. The official languages are English, French and Spanish; any language, however, may be used. The International Council of Ophthalmology has agreed upon two main discussions on the following subjects: (a) the role of the sympathetic system in the genesis of vascular hypertension and its effect upon the eye, (b) the clinical and social aspects of heredity in ophthalmology. Those desirous of participating in the main discussions or reading communications on other ophthalmological subjects should communicate with Mr Keith Lyle, International Congress of Ophthalmology, 45, Lincoln's Inn Fields, London, WC2.

### Malta Hospital Rebuilt

The King George V Merchant Seamen's Memorial Hospital in Malta has been rebuilt and was opened by Lady Mountbatten on Nov 30. The hospital was originally opened in 1922 and was intended chiefly to serve the needs of merchant seamen. In addition, however, it has always cared for the personnel of the Royal Navy and their families, and residents and visitors to the Island. It was destroyed by enemy action on April 7, 1942. The Scottish Branch of the British Red Cross Society contributed £125,000 to rebuilding the hospital, and other organizations and friends have contributed large sums.

### Historic Medical Diary

On display in the rare manuscripts room at the British Museum are the diaries and papers from Scott's last expedition. An interesting item is the 1910 'Wellcome' Medical Diary carried throughout his journey by Dr E. A. Wilson, medical officer to the party. As legible as if it had been written to-day, it forms a record of personal and scientific observation second in importance only to Captain Scott's own papers. The diary was found in the tent where the South Polar explorers met their end.

### Radioactive Tracers for Germany

A contract for the supply of radioactive tracers to approved research institutes in the Bizone has recently been placed with the Atomic Energy Research Establishment, Harwell, by the Joint Export Import Agency. This follows the decision of the Isotope Allocation Committee of the Ministry of Supply in January last that radioactive tracers produced in the Harwell 'gleep' could be made available for research work in Germany. The decision of the Isotope Allocation Committee was communicated to the authority responsible for the control of research in the British Zone who immediately informed the US Research Control Group. Together they approached the Board of J.E.I.A. supported by their respective public health advisers, and with the minimum of delay the Board authorized the import of radioactive tracers from Harwell into the Bizone. Research institutes in the Bizone thus gain access to a range of radioactive tracers the indigenous production of which is denied to Germany under Control Council Law No. 25 for the Control of Research. Their allocation within the Bizone is the responsibility of a small German committee competent to decide where proper use will be made of the small total supply of tracers at present available. In order to assist the committee in its task a team of experts from A.E.R.E. visited Germany during October demonstrated the latest ancillary equipment, and answered many queries put to them by the committee.

### Admission to Roll of Assistant Nurses

The General Nursing Council for England and Wales announces that people wishing to apply as assistant nurses with intermediate qualifications for admission to the Roll of Assistant Nurses set up under the Nurses Act 1943, must do so before Jan 1, 1949. After that date only those people who have undergone two years' training as pupil assistant nurses in a training school approved by the council and have passed a test laid down by the council will be admitted to the Roll. Under the Waver Rule applicants who would have been eligible for enrolment as existing assistant nurses but who failed to apply before Feb 3 1946 may now be considered for enrolment. Information may be obtained from the Registrar, General Nursing Council for England and Wales, 23, Portland Place, London, W1.

## THE PRACTICAL EXPRESSION OF NUTRITIONAL PRINCIPLES

A sensible balance of protein, fat and carbohydrate, a sufficiency of mineral salts, adequate vitamin nutrition—all these are factors of first importance in the infant diet. Farex takes these factors into full account. Three cereals are blended in Farex with extra iron, calcium and vitamin D, forming a bland, smooth food that is ideally suited to the young digestion. That is why it has won such acceptance as a weaning food. These same nutritional merits make Farex eminently suitable for the sick and convalescent. Farex provides for them a 'square' meal yet a 'light' meal. Moreover, Farex needs no cooking—a particular advantage to the unattended patient.

# Painless INTRAMUSCULAR INJECTIONS

eg of PENICILLIN, LIVER EXTRACTS,  
ARSENO-BENZOLS, BISMUTH, etc.

Many substances create some pain on intramuscular injection. Novutox injected at the same time will prevent this pain.

Most substances are compatible with Novutox, which is also non-destructible to penicillin during the time that the latter is undergoing absorption.

Mixtures with Novutox should be made  
immediately before use **ONLY**

## NOVUTOX

*Self-Sterilising  
Local Anaesthetic*

Each cc of Novutox 2% contains 0.02 gm ethocaine hcl, 0.00002 gm epinephrine and 0.00002 gm capryl hydrocupreinatoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

## PROTEIN THERAPY IN ALLERGIC DISORDERS

Specific Protein Therapy shows many advantages over the earlier forms of non-specific treatment for allergic disorders such as asthma, hay fever, migraine, etc.

Allergen Diagnostic Test Solutions—Duncan are issued in simple or multiple group tests. Comprehensive outfits are supplied containing a 2 cc. bottle of each multiple test and provide a valuable method of diagnosing allergic disorders.

## 'PERNIVIT'

*Tablets of Acetomenaphthone  
and Nicotinic Acid B D H*

Considerable success in the treatment of chilblains has been reported following the use of acetomenaphthone in one group of patients and of nicotinic acid in a second group.

It may be that abnormal venous permeability and prolonged blood clotting time on one hand and venous stasis from vasoconstriction on the other may both be contributory causes of chilblains.

Trial of a combination of acetomenaphthone and nicotinic acid collaterally, therefore, seems justified. 'Pernivit' is now available as tablets, each containing

Acetomenaphthone	7 mg
(Prokayvit Oral)	
Nicotinic Acid	25 mg
Bottles of 50 and 500 tablets

Elastoplast Technique was evolved with Elastoplast Bandages and Dressings. The successful results described in medical and surgical publications were achieved with Elastoplast Bandages and Dressings.

The combination of the particular adhesive spread with the remarkable *stretch* and *regain* properties of the woven fabric, together provide the precise degree of *compression* and *grip* shown by clinical use to be essential to the successful practice of the technique.

These properties, peculiar to Elastoplast, have produced a bandage used for many years with outstanding success by the Medical Profession throughout the world.

## Marriage Guidance

The 'Report of the Departmental Committee on Grants for the Development of Marriage Guidance' has just been published. The Committee, which was set up in February of this year by Mr Chuter Ede, recommends that the work in marriage guidance of the National Marriage Guidance Council, the Catholic Marriage Advisory Council, and the Family Welfare Association should be given help from public funds. It is suggested that these three bodies should together devise schemes for selecting and training persons who are acting as marriage counsellors. It is proposed also that ministers of religion might be allowed to take advantage of these schemes of training. The three organizations are not to lose their identities, and Government grants are recommended of £5,000 a year for the National Marriage Guidance Council and £1,500 a year for the Family Welfare Association and the Catholic Marriage Advisory Council. The Committee proposes that the grants should be reviewed from year to year over an experimental period. The setting up of local centres for marriage guidance is recommended, and it is proposed that such centres should be supported financially by the local authority, one half of any substantial expenditure incurred by the local authority being met by a Government grant.

## Dr E H Taylor Cummings

Dr E H Taylor Cummings, MBE, JP, was elected Mayor and Alderman of the Municipality of Freetown, Sierra Leone, on Nov 16.

## Dr G M Findlay

Dr G M Findlay, editor of the B.M.A. Abstracting Service, has been elected a Corresponding Member of the Société de Pathologie Exotique.

## Sir Arnold Stott

Sir Arnold Walmsley Stott, KBE, BCh, FRCP, has been appointed an Extra Physician to the King's Household.

## New Sheriffs

David Rhys Lewis, MD, FRCPed, has been nominated a Sheriff in the County of Breconshire, and Dyfrig Huws Pennant, DSO, MD, in the County of Pembrokeshire.

## Director General of Unesco

Señor Torres Bodet, Foreign Minister of Mexico, has been elected Director General of Unesco in succession to Dr Julian Huxley. Señor Bodet was the only candidate.

## COMING EVENTS

## South West London Medical Society

The third clinical meeting of the session will be held at the Boleyn Hospital at 8.15 p.m. on Wednesday, Dec 8, when Mr Wm A Hervey will lecture on 'Fenestration—Hearing Aids'.

## Public Health Centenary

The centenary of the Public Health Act, 1848, will be celebrated by the Trustees of the Chadwick Trust at the Royal Society of Tropical Medicine and Hygiene (26, Portland Place, London, W) on Tuesday, Dec 14, when tea and cocktails will be served between 4 p.m. and 6 p.m.

## Rheumatic Diseases Conference

The 7th International Congress of Rheumatic Diseases will be held in New York City on May 30—June 3, 1949, under the auspices of the International League against Rheumatism. The invited guests will be the members of the International League, the European League, and the Pan-American League against Rheumatism with their constituent organizations, the Canadian Rheumatism Association, the British Empire Rheumatism Council, the Heberden Society of London, the Rheumatism Societies affiliated to the American Rheumatism Association, and certain individuals. Prospective participants who intend to present papers should submit titles of their papers to the Programme Committee before Jan 1, 1949. Information may be obtained from Dr Ralph Pemberton, 1901, Walnut Street, Philadelphia, Pennsylvania, U.S.A.

## SOCIETIES AND LECTURES

## Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Edinburgh Royal Infirmary (West Medical Lecture Theatre), Dec 7, 5 p.m. *A Scholar's View of Immortality* by Professor O L Richmond.

EUGENICS SOCIETY—At Royal Society, Burlington House, Piccadilly, London, W, Dec 7, 5.30 p.m. *Maternity in Britain: The Results of a Social Survey* by Dr J W B Douglas. All interested are invited to attend.

GLASGOW UNIVERSITY—Dec 7, 4.30 p.m. *Medicine in Literature* by Dr Douglas Guthrie.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Dec 7, 5 p.m. *Hysteria Cutis* by Dr W J O'Donovan.

INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street, London, W.C., Dec 7, 11 a.m. *Interpretation of Serological Reactions for Syphilis*, by Dr R Thomson, at St Peter's Hospital, Henrietta Street, London, W.C., Dec 7, 5 p.m. *Non-gonococcal Urethritis*, by Dr A H Harkness.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Dec 7, 5 p.m. *The Pestilences of War—I The Early Civilizations and Greece*, FitzPatrick Lecture by Dr W H Wynn.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, London, W.—Dec 7, 3 p.m. *The Physiology of Haemopoiesis*, Harben Lecture by Sir Lionel Whitby.

## Wednesday

BRITISH PSYCHOLOGICAL SOCIETY—At Royal Society of Medicine, 1, Wimpole Street, London, W., Dec 8, 8 p.m. Meeting of Medical Section. *The Changing Functions of a Psychiatric Out-patient Department*. Symposium by Drs Elizabeth Rosenberg, O W S FitzGerald, and Sir Paul Mallinson.

INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street, London, W.C., Dec 8, 11 a.m. *Biological False positive Serum Reactions* by Dr R Thomson, 5 p.m., *Fistula Carcinoma and Foreign Bodies of the Urethra and Injuries of the Urethra* by Mr C H Mills.

PHYSICAL SOCIETY COLOUR GROUP—At Large Physics Lecture Theatre, Imperial College, Imperial Institute Road, London, S.W., Dec 8, 3 p.m. 43rd Science Meeting of Group. *The Scotopic Visibility Function* by Dr B H Crawford. *Visual Purple and the Photopic Luminosity Curve* by Dr H J A Dartnall.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, 242 St Vincent Street, Glasgow—Dec 8, 5 p.m. *Polymyositis* by Professor J C Spence.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, London, W.—Dec 8, 3 p.m. *Dyschaemopoiesis from Nutritional and Specific Deficiencies*. Harben Lecture by Sir Lionel Whitby.

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace Road, London S.W.—Dec 8, 2.30 p.m. *Food Hygiene: Ideas for the Future*. Discussion to be opened by Councillor William L. Roots and Mr H W Walters.

UNIVERSITY COLLEGE, Gower Street, London, W.C.—At Physiology Theatre, Dec 8, 5.15 p.m. *Statistics from the Standpoint of a Pharmacologist* by Dr J W Trevan, F.R.S.

## Thursday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Dec 9, 5 p.m. *Seborrhoeic Dermatoses* by Dr J L Franklin.

INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street, London, W.C., Dec 9, 11 a.m. *Treatment of Syphilis* by Dr W N Mascall, 5 p.m., *Injuries and Diseases of the Penis other than Venereal* by Mr A R C Higham.

PLANNING FORUM—At Planning Centre Hall, 28, King Street, Covent Garden, London, W.C., Dec 9, 6.15 p.m. *Manpower* discussion to be opened by Mr A E U Maud and Mr G D N Worswick.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Dec 9, 5 p.m. *The Pestilences of War—II The Roman Republic and Empire*, FitzPatrick Lecture by Dr W H Wynn.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—Dec 9, 5 p.m. *The Reactions of Bone to Metal*, Robert Jones Lecture by Sir Reginald Watson Jones.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, London, W.—Dec 9, 3 p.m. *Dyschaemopoiesis from Noxious Agents*. Harben Lecture by Sir Lionel Whitby.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, SCIENTIFIC AND TECHNICAL GROUP, 16, Prince's Gate, London, S.W.—Dec 9, 7 p.m. *The Action of X Rays and Electrons on the Photographic Emulsion* by Dr R H Herz.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE—At 26 Portland Place, London, W., Dec 9, 7.30 p.m. *A Survey of Physiological Studies of Mental and Physical Work in Hot and Humid Environments* by Professor G Crowden. A discussion will follow.

ST GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—Dec 9, 4.30 p.m. *Neurology and Psychiatry*. Lecture-demonstration by Dr Desmond Curran.

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP—At London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C., Dec 9, 7 p.m. *The Chemistry of Plant Growth Regulators* by Dr W A Sexton.

## Friday

LONDON CHEST HOSPITAL, Victoria Park, E.—Dec 10, 5 p.m. *Mediastinal Tumours* by Dr J Smart.

MAIDA VALE HOSPITAL MEDICAL SCHOOL, Maida Vale, London, W.—Dec 10, 5 p.m. Case demonstration by Mr Valentine Loeue.

ROYAL MEDICAL SOCIETY, 7, Melbourn Place, Edinburgh—Dec 10, 8 p.m. Hat night.

WEST KENT MEDICO-CHIRURGICAL SOCIETY—At Miller Hospital, Greenwich High Road, London, S.E., Dec 10, 8.30 p.m. *New Chemotherapeutic Substances of Microbial Origin*. Presentation by Sir Howard Florey, F.R.S.

No 46

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov 13

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	33	7	12	3	—	40	2	26	1	—

Whooping cough* Deaths	2 481	152	101	56	10	1 217	70	43	36	7
Deaths (0-1 year) Infant mortality rate (per 1 000 live births)	279	35	42	22	12	378	47	51	32	20
Deaths (excluding still births) Annual death rate (per 1 000 persons living)	4 876	801	658	171	118	4 582	742	593	179	118
Live births Annual rate per 1 000 persons living	7 065	112	851	417	180	7 781	1260	907	312	224
Stillbirths Rate per 1 000 total births (including stillborn)	179	20	30	—	—	196	28	29	—	—

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county) will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county) and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county) are combined.

|| Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

## Discussion of Table

In England and Wales an increased incidence was recorded for measles 733 whooping cough 241, acute pneumonia 83, and dysentery 78.

The increase in the notifications of measles was due to a few counties, in the remainder of the country only slight variations occurred. The largest increases were Lancashire 390, Yorkshire East Riding 107, Derbyshire 93, and Suffolk 54.

The largest rises in the incidence of whooping cough were 80 in Lancashire and 57 in Wales. The rise in Wales was due mainly to an outbreak affecting 37 persons in the rural districts of Twpelyn and Valley in Anglesey.

The chief feature of the returns of diphtheria was an outbreak of 12 cases in Yorkshire West Riding, Hoyalnd Nether U.D. No large fluctuations in the notifications of scarlet fever were recorded. The largest rise in the incidence of acute pneumonia was 32 in Yorkshire West Riding.

No further case of typhoid was notified in Shropshire, Oswestry R.D., where the outbreak which had persisted for the preceding nine weeks had resulted in 105 notifications.

Fresh outbreaks of dysentery during the week were notified from Essex, Hornchurch U.D. 60 and Cornwall, Truro R.D. 7. An increase of 12 in the cases of dysentery was reported from London, where the notifications were distributed over nine boroughs. The only other large return of dysentery was Lancashire 19.

Acute poliomyelitis declined from 73 to 60 notifications. The largest returns were Durham 7, Lancashire 4, and Middlesex 4.

In Scotland rises occurred in the notifications of acute primary pneumonia 13, whooping cough 12, and paratyphoid fever 11, while decreases were recorded for measles 47 and scarlet fever 12. All the 17 cases of paratyphoid fever were notified in the city of Aberdeen. The chief centres of dysentery were the cities of Glasgow 31 and Edinburgh 14.

In Eire decreases in the notifications of measles 74 and whooping-cough 16 were the chief features of the returns. A fall of 11 was recorded in the notifications of diarrhoea and enteritis in Dublin C.B.

In Northern Ireland the notifications of measles in Belfast C.B. were 29 fewer than in the preceding week.

## Week Ending November 20

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,835, whooping-cough 2,680, diphtheria 154, measles 6,923, acute pneumonia 732, cerebrospinal fever 32, acute poliomyelitis 46, dysentery 49, paratyphoid 4, and typhoid 9.

## BIRTHS, MARRIAGES, AND DEATHS

## BIRTHS

Calvert Smith.—On Sept 18 1948 at Daphne (ofc Bousfield) M.B. B.S. wife of John E. Calvert-Smith M.A. of 60 Hall Farm Drive Whitton Middlesex a son—Colin Paul.

Cane.—On Nov 17 1948 at Tabora Tanganyika to Margaret wife of Dr Hugh Cane a son.

## DEATHS

Bonavia.—On Nov 20 1948 at No 94 British Military Hospital Hamburg Victor Joseph Bonavia M.D. MRCP Colonel late R.A.M.C. aged 54.

Deuchars.—On Nov 20 1948 at 38 Hope Terrace Edinburgh James McGavin Deuchars M.B. Ch.B. Ed.

Hamilton.—On Nov 12 1948 at 205 East 61st Street New York George Johnson Hamilton M.D.

Heath.—On Nov 16 1948 at 9 Highdown Avenue Worthing Wrotham Gerald Heath M.B. Ch.B. Ed. aged 75.

Kitchin.—On Nov 22 1948 Percy Kitchin MRCS LRCP of 86 Sea Lane Goring by Sea aged 78.

Maples.—On Nov 16 1948 at 7 Windsor Crescent Jersey Ernest Edgar Maples M.D. FRCS.

Moseley.—On Nov 21 1948 at Ipswich Charles Kingston Moseley MRCS LRCP aged 84.

Oakman.—On Nov 22 1948 at a nursing home in Hove Joseph John Oakman MRCS of Rutlands Upper Shoreham Road Shoreham by Sea Sussex aged 84.

Palmer.—On Nov 22 1948 at Morningside Prestbury near Cheltenham Harold Thornbury Palmer MRCS LRCP D.D.M.S. Nigeria retired.

Pictou.—On Nov 19 1948 at Holmes Chapel Cheshire Lionel James Pictou O.B.E. B.M. Ch. aged 74.

Roberts.—On Nov 20 1948 at Northbrook Pangbourne Berks Harry Triet Roberts L.M.S.S.A. L.D.S. R.C.S. late of 31 Harley Street London W.

Robertshaw.—On Nov 21 1948 Walter Midgley Robertshaw M.B. Ch.B. Ed. of Knoll Top Stocksbridge Sheffield aged 78.

Rozelaar.—On Nov 21 1948 at 3 Gillingham Road London N.W. Abraham Levie Rozelaar MRCS LRCP.

Waddy.—Recently Frederick Henry Waddy M.D. GLs formerly of Sheffield aged 79.

Wallington.—On Nov 17 1948 at sea Kenneth Trautman King Wallington MRCS LRCP.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Classification of Pulmonary Tuberculosis

**Q**—What is the classification of pulmonary tuberculosis of the National Tuberculosis Association of America, and how does this compare with the latest Ministry of Health classification in this country?

**A**—The classification of pulmonary tuberculosis of the National Tuberculosis Association of America was revised in 1940, when the terms 'primary phase' and 'reinfection phase' replaced 'childhood type' and 'adult type'. The features of previous classification relating to extent of lesions and symptomatology were preserved, but definitions were made more comprehensive and those relating to results of treatment were more rigidly specified. The definitions and classifications may be briefly summarized as follows:

**Primary Phase**—That phase of the morbid process which follows directly and uninterruptedly the first implantation of tubercle bacilli. It may occur at any age and may be symptomless. There may be no clinical or radiological signs, but, on the other hand, the infection may be grave.

**Reinfection Phase**—This follows the primary phase usually after a latent period, and comprises the lesions which develop after re-infection with tubercle bacilli, which are derived from five potential sources: (a) outside the body, (b) from a breakdown of the primary focus, (c) by rupture of a caseous lymph node by way of the lymphatics and the blood stream, (d) from the small apical foci resulting from early haematogenous dissemination becoming progressive after having been stationary or undetected for a long period of time.

**Pulmonary Lesions**—These are classified as: (1) *Minimal*—Slight lesions without demonstrable excavation confined to a small part of one or both lungs, the total extent of the lesions, regardless of distribution, shall not exceed the equivalent of the volume of lung tissue which lies above the second chondro sternal junction and the spine of the fourth or body of the fifth thoracic vertebra on one side. (2) *Moderately advanced*—One or both lungs may be involved, but the total extent of the lesions shall not exceed the following limits: (a) slight disseminated lesions which may extend through not more than the volume of one lung, (b) dense and confluent lesions which may extend through not more than the equivalent of one third the volume of one lung, (c) any gradation within the limits of a and b. Total cavities, if present, should not exceed 4 cm. (3) *Far advanced*—Lesions more extensive than moderately advanced.

**Clinical Status**—Under this heading five definitions are stated:

(1) *Apparently Cured*—In which constitutional symptoms are absent and sputum, if any, must be negative for tubercle bacilli, not only by concentration and microscopical examination, but also by culture and animal inoculation. In case there is no sputum, the fasting gastric contents should be obtained and similarly examined. Lesions must be stationary and apparently healed according to x-ray examination. These conditions shall have existed for a period of two years under ordinary conditions of life. (2) *Arrested*—Constitutional symptoms absent, sputum, if any, must when concentrated be microscopically negative for tubercle bacilli, lesions stationary and apparently healed according to x-ray examination, no evidence of pulmonary cavitation. These conditions shall have existed for a period of six months, during the last two of which the patient has been taking one hour's walking exercise twice daily or its equivalent. (3) *Apparently Arrested*—Clinical conditions demanded for "arrested" shall have existed for a period of three months, during the last two of which the patient has been taking one hour's walking exercise daily or its equivalent. (4) *Quiescent*—No constitutional symptoms, sputum, if any, may contain tubercle bacilli, lesions stationary or retrogressive according to x-ray examination, cavity may be present. These conditions to have existed for at least two months, during which time the patient has been ambulant. (5) *Frankly Active*—Improved, unimproved, symptoms unchanged, worse or less severe, but not completely abated. Lesions not completely healed or progressive according to x-ray examination. Sputum almost always contains tubercle bacilli. (6) *Dead*.

The US classification has had to be given in considerable detail, otherwise it would be difficult to point out how that of the Ministry of Health differs from it. The fundamental difference between the Ministry's classification and the American one is that the former is based on the finding, or failure to find, the tubercle bacillus in the lesion, thereby dividing tuberculous persons into two classes: (a) the non-infectious, in whom the tubercle bacillus has never been found, and (b) the infectious class, in whom the bacillus has been found. Both classes are subdivided into three groups (1, 2, and 3) according to the radiological extent of the lesion and the severity of the symptoms. Cases of pleural effusion in which there is an absence of severe constitutional disturbances, failure to find tubercle bacilli in the pleural fluid, and no parenchymatous lesion are placed in Group 1 of Class A. Where a single positive bacteriological report is not confirmed by further bacteriological search and is unsupported by clinical or radiological evidence of tuberculosis it may be ignored. Considerable difference exists in the definitions of "quiescence". The one adopted by the Ministry of Health reads:

"Cases in which the general condition and exercise tolerance are good, having regard to the extent of the lesion which show no evidence of toxæmia, in which no tubercle bacilli have been found on three consecutive monthly examinations by stained film and in which changes revealed by other clinical investigations and by serial skiagrams point to retrogression of the tuberculous lesion."

A case is not accepted as "recovered" until a state of quiescence has been maintained without interruption for five years. The term 'active' is described by a negative definition as the state that is not quiescent. All cases discharging tubercle bacilli within the preceding three months should be considered as 'active'. A stationary case is one in which the signs, symptoms, clinical tests, and radiological appearance of the lesion have presented no material new feature during the period under review.

To draw up a classification which will satisfactorily include all cases of tuberculosis is a difficult task, and many attempts have been made to produce a comprehensive scheme, but none up to the present meets all requirements. Both the one of the National Tuberculosis Association and that of the Ministry of Health are practical classifications with limited application, but are useful and satisfactory for statistical work on an extensive scale.

### Leukoplakia and Kraurosis Vulvæ

**Q**—What are the present definitions of leukoplakia and kraurosis vulvæ? Which is the commoner? What are the modern figures for the relationship between each of these two conditions and malignancy?

**A**—Although the general opinion on these two conditions is still based on the views put forward by Berkeley and Bonney in 1909 (*British Medical Journal* 1909, 2, 1739, *Proc R Soc Med* 1909, 3, 29) there remains a good deal of doubt and confusion. Indeed, there are signs of a reorientation of ideas during the last few years, and this tends to increase the uncertainty. Kraurosis vulvæ is to be regarded as a condition of extreme atrophy and contracture of the introitus, sometimes complicated by secondary infection. It might be considered as an exaggeration of the normal senile atrophy, and for all practical purposes it occurs only after suppression of ovarian activity. It is conceivable, however, that it might arise before the menopause if for some reason the vulva loses its ability to respond to oestrogens. In the typical menopausal case the lesion responds to oestrogens but recurs when they are withheld. It does not predispose to cancer. Its occurrence is rare as compared with that of leukoplakia.

Leukoplakia vulvæ is characterized by excessive keratinization of the skin, which becomes thickened, white, and hard and tends to crack, and it is not strictly confined to the introitus. In the deeper layers of the dermis, in the later stages of the disease at any rate, there are degenerative changes, and the appearances suggest that the nutrition or blood supply of the epidermis is impaired. It is doubtful whether the four separate pathological stages of the lesion as described by Berkeley and Bonney really exist. It was formerly thought to be a definite clinical entity of unknown cause, possibly a manifestation of chronic infection but not syphilitic. There is now a good deal of

evidence to suggest that the skin changes represent a non specific reaction to a large number of possible factors. Among these factors deficiency states may be important, so 'leukoplakia' is sometimes seen as a manifestation of riboflavin deficiency, iron deficiency anaemia, achlorhydria or macrocytic anaemia, and clears up when the missing factor is replaced. Sometimes, perhaps, the deficiency is a local rather than a general one, and results from an interference in blood supply to the vulval skin or from a failure of the tissues to utilize the factor concerned. Scratching by the patient in response to pruritus vulvae of any origin may also account for some of the skin changes. Leukoplakia can occur at any age and is probably not related to failure of ovarian function, it is not improved by oestrogen therapy. These are some of the lines of modern thought, the ideas are attractive, but many await proof.

Unlike kraurosis, leukoplakia is a precancerous condition, and that at any age. It is impossible to give reliable statistics about how often cancer is superimposed, but it is frequent enough to justify excising areas of leukoplakia which do not respond readily to medical treatment. There are figures showing that established carcinoma of the vulva is very frequently associated with leukoplakia in adjacent areas of skin, suggesting that leukoplakia preceded the growth. Berkeley and Bonney (*loc cit*) said they had never seen a case of carcinoma without there being evidence of leukoplakia as well. F J Tausig, the American authority on this group of diseases, found leukoplakia to be present in 50% of cases, while S Way (*Ann Roy Coll Surg Eng* 1948, 3, 187), in his recent report on a comparatively large series of cases of cancer of the vulva, puts the figure at 78%.

#### Fattening the Lean

**Q**—*Is there any treatment which will increase the weight of very thin people who appear to have no other abnormalities? A man of 30 weighs 9 st 7 lb (60.3 kg) and is 6 feet (1.8 m) tall. He has been this weight for twelve years. An office worker, he is very fit but tires rather easily. He has no relevant previous history and his diet seems to be adequate. He asks if insulin injections would be helpful.*

**A**—The problem of increasing the weight of the abnormally thin is complementary to that of reducing the weight of the abnormally fat. Assuming the absence of morbid causes, in the latter the intake of calories exceeds the output, in the former, the reverse. Many believe that constitutional factors are important: that in some, absorption is unduly efficient or utilization greater. No evidence exists to suggest that these views are correct. In the absence of disease the tendency to gain or lose weight appears to be a simple function of the quantity of food eaten and the amount of energy expended in work. It depends, that is, on appetite, and appetite is a habit without close correlation to the energy output of the body. While those who gain weight always eat more than they need, it is proverbial that they invariably claim to eat "hardly a thing". Similarly, careful analysis of the exact quantities eaten by those who are unduly thin will show that the calorie intake is low. They will seldom agree that they eat insufficient, and they do indeed take enough to assuage their small appetites. It will be found that if a diet of sufficient calorie value is taken the thin will certainly gain weight.

In the present instance the mean normal weight for a man of 30 years, 6 feet tall is 12 st 4 lb (78 kg). He is thus 39 lb (17.6 kg) under weight. The estimated basal requirements of a normal man of this age and height would be 1,920 calories, average requirements for a moderately active life are a little above twice the basal values. If he took a diet of 3,800 calories there is little doubt that his weight would rise to normal levels. Insulin has the effect of increasing appetite and might be of value in this respect.

#### Phosphaturia

**Q**—*What is the best treatment for phosphaturia? What measures should be taken to counteract it?*

**A**—Phosphates are of course, present in normal urine, and it is quite usual for phosphate salts to be deposited when the urine cools. Sometimes phosphates come out of solution before the urine leaves the bladder and the urine is then cloudy when passed. This is not indicative of any state of ill-health and has

not been shown to predispose towards the formation of calculi. It therefore requires no treatment, but if it worries the patient it can be prevented by acidifying or diluting the urine. This could be done by taking more fluid and a diet containing more protein and less fruit and vegetables. Acidifying salts such as ammonium chloride would have the same effect but there is no reason to give these unpleasant remedies for this harmless symptom.

#### Quinidine, Dicoumarol, and Auricular Fibrillation

**Q**—*In view of the serious consequences which may follow embolism in cases of auricular fibrillation treated with one of the digitalis compounds is it justifiable to give a course of dicoumarol at the onset of the digitalis therapy? If so for how long and in what dosage? Does digitalis act on the blood by increasing the clotting power or is it simply that thrombi are more likely to be discharged from the auricles as a result of the altered action of the heart under the influence of digitalis?*

**A**—Digitalis compounds do not in themselves increase the likelihood of embolic phenomena when given in cases of auricular fibrillation. Digitalis increases coagulability of the blood to such a slight degree that it has no clinical significance. In the case of quinidine, which apparently is the drug in mind, embolic phenomena may follow its use. This danger depends on the presence of pre-formed thrombi in the auricular appendages, which are expelled when the auricles revert to sinus rhythm. Its danger is not removed by a course of dicoumarol, but may be avoided in part by the careful selection of cases for quinidine therapy. This drug should not be given to a patient known to be fibrillating for eighteen months or longer who has been in congestive failure, who has already suffered embolic accidents, or who has severe cardiac damage.

#### NOTES AND COMMENTS

**Herpes after Coryza**—Dr M A DOBBIN CRAWFORD (London, WC) writes "I was interested in the question and answer under this heading ('Any Questions?' Oct 16, p 730). I am convinced that in the majority of cases this condition is due to superficial irritation of the skin about the nose and lips by the catarrhal nasal discharge—very probably infective. The typical blister reaction can be completely prevented by the use of a suitable barrier cream from the start of the cold. The best I have found is a sulphacetamide ointment. If applied freely at night and when possible during the day there will be no herpes. In cases where the skin is already blistered it should be dried and cleaned by frequent application of spirits of camphor, eau de cologne or methylated spirits followed by the use of the sulphacetamide ointment.

**Physiology of Hearing**—Dr R S CREED (Oxford) writes "The answer (Nov 6, p 846) to the request for information about the specific gravity and viscosity of the cochlear fluids may be supplemented as follows. In both shark (Kaieda, J. *Hoppe Seyl Z* 1930 188, 193) and pigeon (Rossi, G, *Arch Fisiol* 1914, 12, 415) endolymph has been found to be much more viscous than perilymph. In the shark they have the same specific gravity (1020), slightly lower than that of cerebrospinal fluid (1023). Other details of chemical and physical properties are given by Kaieda, and by Gerhartz in Oppenheimer's *Handbuch der Biochemie* (1925 4 182 Jena).

**Christmas at Barnardo's**—In Dr Barnardo's Homes 7,000 children are making plans for Christmas. The Homes would gratefully receive gifts of toys or money, which should be sent to Barnardo House, Stepney Causeway, London, E 1.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. # SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 4 1948

## THE SECRETARY REPORTS\*

### REMUNERATION

The Conference of Local Medical Committees, a report of which appears on subsequent pages, expressed with clarity and vigour the views of general practitioners in the Service. On remuneration generally the demand and the decision were to press immediately for the full application of the Spens Report. The special inquiry into the range of income in a large county area is likely to be completed within a day or two of the appearance of these words in print. Armed with this information the General Medical Services Committee will press for an all round improvement in remuneration. The urgent pressing problems concerning the small-list practitioner were emphasized again and again, the general trend of opinion being that the solution lies in an improvement of remuneration generally, plus an increase in the Mileage Fund.

The mileage issue comes under the general heading of 'Spens,' as is illustrated by the following paragraph from that Report:

"So far, we have discussed solely the position in regard to urban practices. We do not regard as significant the comparatively small differences which Professor Bradford Hill's figures indicate as between urban and mixed practices. The latter have produced somewhat larger incomes, but the difference is not great, and it is far from clear whether this difference would persist in a publicly organized service. A more serious problem exists in regard to incomes from rural practices. We are not prepared to criticize the existence of a difference between the average remuneration of rural and urban practice, having regard to differences in cost of living and amenities, but we consider that the difference of approximately £200 which existed in 1939 between incomes about the £1,000 level in the two classes is excessive and requires reduction by about half, when regard is had to all the facts involved. It appears probable that this could best be secured by weighting mileage more heavily."

Clearly the disparity between urban and rural incomes has substantially increased as a result of the virtual disappearance of private practice and the increased number of items of service being demanded by patients in rural, as in urban, areas. It was obvious that the Conference preferred a permanent solution of the problem rather than special inducements though few will deny that the Special Inducement Fund can and should be used to deal with immediate hardship pending a more permanent solution.

Another point which was pressed—it was made to the Ministry months ago—is that the Mileage Fund cannot be regarded as merely a part of a larger medical fund but is something which stands by itself to be used for the purpose of compensating rural practitioners for the time, as well as the cost, of travelling.

#### Basic Salary

The basic salary position had a debate to itself. It was generally agreed that a system under which the final decision on the disposal of local moneys belonging to local practitioners rested with the Minister was wrong. So far some 11 appeals have been made to the Minister and he has allowed 8 of them.

\*Under this heading the Secretary of the Association will at regular intervals—at present weekly—give an account of the efforts being made to place the new Health Service on a basis which is satisfactory to the profession. These reports will, it is hoped, supplement the items of news which appear in these columns, providing background and explanation.

some 80 appeals remaining outstanding. It was said that some local medical committees regarded the task of considering and making recommendations on applications as invidious and likely to divide the profession. There were suggestions to transfer this work of considering applications to the centre, some resolutions advocating payment from a separate fund, others payment from the existing Central Practitioners Fund. In one unusually effective speech strong arguments were put forward against such a translation. In effect they were that under Spens any money found for basic salaries is bound to come out of the professions remuneration and that if a separate fund is created for basic salaries it will be by subtraction from the Central Practitioners Fund. This being so, however unpleasant the work, we should keep this matter in our own hands and, because of the importance of local knowledge, in the hands of the local medical committee. To pass it to the centre aggravated the danger of a universal basic salary. After all one of our major gains was the withdrawal of the proposal for a universal basic salary, and it would be tragic if we found ourselves pressing for it in order to meet current difficulties. The General Medical Services Committee is reviewing the whole matter in the light of the Conference's discussion on Thursday Dec 2. There was general agreement on the point that once remuneration and mileage were established on a proper basis providing adequate incomes in all kinds of area, the basic salary issue would tend to recede in the background, except in the special circumstances about which there is no dispute.

The question of the heavy burden of work in relation to the permitted maximum came up, and the general view was that the first and paramount task was to secure the proper application of Spens with an adequate betterment factor applied to the recommendations.

### Hospital Conditions of Service

At last the Ministry's proposed terms and conditions of service of hospital medical and dental staff—marked 'confidential'—have been sent to the Negotiating Committee which in turn has circulated them to the Councils of the Royal Colleges and the Royal Scottish Corporations and the Central Consultants and Specialists Committee for their observations.

### Committee on Partnerships

A fairly full analysis of the report of the Legal Committee on Partnerships is published in these columns this week. The report is unusually complicated, though it is written with great skill and clarity. It amply justifies the complaint made by the professions representatives to the Minister again and again that the section of the Act stated to deal with partnerships is ambiguous and obscure, so much so that the Legal Committee—presumably believing that no partner could have understood what he was in for—has recommended a new appointed day on which anyone in partnership on July 5, 1948, can decide afresh whether or not to enter the Service, with the same compensation rights as applied to those who entered on the original appointed day. The publication of this report clears away the last obstacle to the production of the amending Bill, and the Minister has been asked when we may expect to be given the opportunity of examining in draft the proposed clauses.

# National Health Service

## TREATMENT OF FOREIGN VISITORS

### COUNSEL'S OPINION

Medical men were surprised to learn from a public announcement issued by the Ministry of Health that they were required under the NHS Act to treat visitors from overseas. One effect of this decision may be to increase the population at risk while returning the same sum for remuneration. The B.M.A. took the matter up with the Ministry, but obtained no satisfaction, and the General Practice Subcommittee of the Negotiating Committee took counsel's opinion on the Ministry's interpretation of the Act. His opinion agrees with the Ministry's.

Counsel began by pointing out that the relevant parts of the Act are Sections 1 and 33. Section 1 speaks of 'the people of England and Wales' as the objects of the Act, and Section 33 requires executive councils to arrange for the provision of medical services for all persons in their respective areas who wish to take advantage of the arrangements. Counsel considers that in order to take advantage of the arrangements under the Act no other qualification is needed than being in the area to which the arrangements relate and wishing to take advantage of them. He found difficulty in justifying any other construction on the words. For example if residence in the area had been required, the Act would have said 'all persons resident, etc.', and even then it would have been difficult to decide what degree of permanence there would constitute residence.

It would be difficult to exclude foreigners as such from the benefit of the Act since a foreigner might be domiciled in England or Wales and habitually resident in an executive council area, so as undoubtedly to be one of the persons in the area. Further if a visitor from one town in England is covered by the Act in another it is difficult to see how Section 33 can be construed to have this result and yet exclude a visitor from overseas.

## LIMITATION OF DOCTORS' LISTS

### COUNCILS TO TAKE ACTION

The Minister of Health after consultation with the B.M.A., has informed local executive councils that they should, as soon as possible review the numbers on the lists of doctors in their areas in consultation with the councils for adjoining areas where necessary. As soon as reasonably practicable the lists should be brought within the prescribed maxima—4,000 for a principal working alone, 6,400 if he employs an assistant under his own arrangements.

Some lists are inflated by the inclusion of names twice over for on July 5 the names on a doctor's panel list were automatically transferred to his NHS list, and some of these people subsequently had their names put on his list again by means of Form EC1. Executive councils should therefore obtain accurate figures as early as possible.

The Minister suggests that as a first step a doctor with too large a list should be asked not to accept additional persons on his list except relatives of those already on it living in the same house, unless he is joined by a partner or employs an assistant or in some other way brings the list within the appropriate limit. In special circumstances an executive council may apply for the Minister's approval to a higher maximum in individual cases.

## MEDICAL PRACTICES ADVISORY BUREAU INFORMATION SERVICE STARTED

The B.M.A.'s new venture to provide doctors with an information service about appointments available has now been started and will be fully functioning at the end of this year. Running at an ultimate estimated cost of up to £10,000 a year the service is free to members of the Association a charge being made to non-members. The Bureau is under the direction of a member of the medical secretariat and inquiries should be addressed to the Secretary of the Association.

Since the Act abolished the buying and selling of the goodwill of practices many problems have arisen on how to enter

general practice. Many doctors are wondering how to set about putting up their plates. For instance, it is said that there is a shortage of doctors and that many areas are insufficiently served where are these to be found? The Bureau hopes to provide doctors with information such as this and to help them find suitable openings or vacancies as principals, assistants or partners. It will also try to supply locums. When working fully it will provide an information service for consultants and specialists as well.

## PAY-BED ACCOMMODATION

### OPERATION FEES

The Executive Committee of the Central Consultants and Specialists Committee discussed the National Health Service (Pay-bed Accommodation) Regulations (No. 1490) at its most recent meeting and expressed extreme dissatisfaction with regard to the third schedule which classifies major, intermediate, and minor operations.

In general, it was the committee's view that it is both inappropriate and inequitable that a schedule of operations should lay down arbitrarily the degree of severity of an operation without reference to the particular case. The committee felt that the whole schedule should be abolished and this view was confirmed as it discussed a number of examples which demonstrate the schedule's inappropriateness and inaccuracies. It is understood that the Regulations were based on the Nuffield Provident Guarantee Fund classification which was drawn up as a general guide for hospital benefit schemes. This scheme, designed for an entirely different purpose, is not applicable for a total payment. The total ceiling on charges is £75, a sum which includes the cost of consultations, pathological and radiological investigation, anaesthetic fees, and so on. If these services are paid for at specified rates, the amounts left to pay for the operation may be very small. On the other hand if the payments for all the services were proportionately reduced, this reduction would be difficult to determine equitably.

No allowance is made for a series of operations—e.g., thoracoplasty or two stage operations. Some operations are entirely omitted, notably those performed by thoracic surgeons—e.g., pneumonectomy, lobectomy, surgery of the heart, and so on. No mention is made of cases where two surgeons and their assistants operate simultaneously, as in abdomino-perineal excision of the rectum. A number of ENT operations are also omitted—e.g., fenestration, trans-antral ethmoidectomy, dacryo-rhinostomy.

The classification of the operations was also criticized. Why, for example, is an epithelioma of the lip with excision of sub-mandibular glands classified as an intermediate operation while the similar operation on the tongue is classified as a major? There is no reference in either case to the extent and degree of the primary condition. The injection of a Gasserian ganglion and the aspiration of a cerebral cyst are considered minor surgical operations equivalent to the opening of an abscess or removal of sebaceous cysts. An internal sinus operation is not mentioned while the external approach is encouraged as a major operation.

It will be agreed that there is no such operation as simple mastoidectomy for the surgeon must be prepared for anatomical variations or pathological changes which may entirely alter the scope of the operation. Removal of tonsils by dissection without the use of guillotine (18 years and over) is classified as intermediate and guillotine removal of tonsils (18 years and over)—an operation perhaps never performed—is charged as a minor operation. No mention is made of the removal of tonsils and adenoids in children.

The time taken on an operation, difficulties encountered, and a variety of other circumstances should all be taken into account in assessing a charge, and the only satisfactory method is to leave it to the judgment of the surgeon. The Central Consultants and Specialists Committee will consider the report of the Executive Committee at the next meeting.

## LEGAL COMMITTEE ON MEDICAL PARTNERSHIPS

### MAIN FEATURES OF REPORT

1 The Minister of Health announced in the House of Commons on April 8 this year that he had appointed an expert Legal Committee to advise him on the disputed effect of the National Health Service Act on partnership agreements. The Minister added "It seems likely that a short clarifying Bill may be needed as a result of its inquiries."

2 The Committee's report was presented to Parliament on Nov 23 as a White Paper (Cmd 7565). The Committee's principal recommendation relates to the differences of opinion as to the effect of Sections 35-37 upon obligations and options contained in existing partnership agreements. While there was room for these differences of opinion a partner who carried out an obligation to buy or sell a share of a practice under his partnership deed might find himself liable to fine or imprisonment, or both. The Committee recommends that existing difficulties and ambiguities should be removed by a declaration that the sections of the Act relating to the prohibition of the sale of practice goodwill and to compensation shall not render unlawful the due fulfilment of obligations, or the exercise of options to purchase goodwill in existing partnership agreements. For this purpose an existing partnership agreement is one relating to a partnership in existence on the appointed day (July 5, 1948) at least one of whose members has his name on the list of an executive council on that day.

3 The Committee recommends that certain modifications should be made in purchase obligations and options except in those cases where the existing partnership agreement makes express provision for the allocation of statutory compensation among the partners. These modifications, however, will not affect restrictive covenants provisions dealing with houses and other property, and other ancillary clauses coming into operation on the sale of a share of a partner's goodwill. For example, where as a result of the modification a sale of goodwill is converted into a free transfer it will be regarded as a sale for the purpose of the agreement, and a restrictive covenant which would have applied to the sale will apply to the free transfer. Thus the free transfer will not affect a clause restraining an outgoing partner from practising within the same area during a prescribed period.

4 The Negotiating Committee of the profession represented to the Minister in November 1947, that acceptance of his interpretation of the Act created two main difficulties:

(a) It is impossible to determine, in advance of the various contingencies which may arise under the usual partnership deed, the amount of compensation "payable to any medical practitioner." Even if it be assumed that the amount of compensation due to a partnership can be calculated it is impossible to calculate the shares of the individual partners.

(b) It is impossible to determine at the appointed day how and to whom interest due on the compensation moneys should be paid.

The Legal Committee clarifies the position by a recommendation that the compensation payable to each partner who is entitled to it, notwithstanding that an existing agreement provides for transfers of goodwill, should be ascertained and attributed to him as at the appointed day by reference to his annual loss as computed under the National Health Service (Medical Practices Compensation) Regulations, 1948. For this purpose the annual loss is based on the partner's share of the average gross yearly receipts of the partnership practice for the last two accounting years immediately preceding the appointed day.

Compensation is normally payable on retirement or death, and the compensation regulations define retirement as meaning retirement from practice as a medical practitioner providing general medical services under Part IV of the Act (or under the corresponding part of the Scottish Act). The Committee considers that this definition should be amended so far as it relates to an inside partner who transfers his share or part of his share of an existing partnership. It accordingly recommends that where the share of an "inside" partner (i.e., one whose name is on an executive council list at the appointed day) is transferred to another partner or partners under an existing

partnership agreement, the "inside" partner should be regarded as having retired from practice in respect of the share so transferred and the compensation attributable to that share should become immediately payable.

5 The modifications of existing purchase obligations and options recommended by the Committee are dealt with under two headings:

(a) *Service partnerships*—i.e., those partnerships existing at the appointed day of which all the partners are "inside" partners,

(b) *Mixed partnerships*—i.e., those partnerships existing on the appointed day of which at least one member is an "inside" partner and at least one member is an "outside" partner (i.e., one whose name is not on an executive council list).

#### (a) Service Partnerships

6 Where in fulfilment of an option or obligation in an existing agreement an "inside" partner acquires the share of another "inside" partner, the contract price of the share "purchased" will be deemed to have been satisfied by the credit to the vendor (or his estate) of the statutory compensation due in respect of that share, and by the payment of interest thereon. The compensation due on the share so transferred will be immediately payable to the vendor, who will be regarded as having retired from practice as regards that share for the purpose of the Compensation Regulations. In brief the partner who would have been the purchaser acquires the share without payment, the vendor receiving immediate compensation in place of the contract price.

#### (b) Mixed Partnerships

7 (i) Where the transfer is from "inside" partners to other "inside" partners only the "free transfer" arrangement will apply, as in the case of service partnerships (under (a) above).

(ii) Where an "outside" partner has the option to purchase a share from an "inside" partner, the option will remain, but where the existing agreement imposes an obligation on the "outside" partner this obligation will be converted into an option. If the option is exercised the "inside" partner will be required to take from the "outside" partner the contract price and this will replace the compensation attributed to the share sold. The "inside" partner will retain any interest (on the compensation sum) that has accrued to him down to the date of the exercise of the option, but the compensation credited to the "inside" partner will be released to the State.

In brief, the "outside" partner under an obligation to purchase a share from an "inside" partner will be relieved of his obligation but will retain an option to purchase the share by paying the contract price, the compensation credited to that share being forfeited to the State. The "inside" partner, if the option is exercised, will receive the contract price and if it is not exercised will retain the compensation already credited to him.

(iii) The Committee points out that it is not clear whether Section 35 prohibits the sale to a third party of the goodwill of an "inside" partner after it has lawfully passed to an "outside" partner. The Committee thinks that there is no reason why an "outside" partner, if the last survivor should not be free to sell the whole goodwill of the partnership practice or so much of it as vests in him, however he has acquired it though it is recognized that he could not transfer to a purchaser any right to the State patients of the practice.

The Committee recommends that it should be made clear that the provisions of the Act prohibiting the sale of goodwill shall not apply to an "outside" partner (or his personal representative) in relation to the goodwill of the partnership which is vested in him (or in his personal representative).

(iv) Where the transfer is from an "outside" to an "inside" partner only, the "inside" partner will remain bound to pay the contract price but will become entitled to be paid compensation out of a Supplementary Compensation Fund. The compensation so payable must not exceed the contract price, but with this reservation it will be assessed proportionately to the compensation already allocated to the "inside" partner's share of the partnership. It is recommended that for the purpose of the Supplementary Compensation Fund additional moneys should be provided by Parliament.

This recommendation meets the Negotiating Committee's criticism that in fulfilling his contractual obligations a practitioner might have been required to buy a partner's private

practice which he could not sell and in respect of which no compensation was payable from the moneys provided under the original Act

### Arbitration

8 The Committee believes that the foregoing recommendations will in general enable an equitable result to be secured as between the members of existing partnerships, but as the application of the principal Act and any amending Act may in certain cases produce special hardships which it is not possible to foresee it recommends that provision should be made for dealing with such hardships as follows

(a) Every existing partnership agreement shall be deemed to contain a clause providing that where a member of the partnership claims that he has suffered or is likely to suffer hardship from the effect of the Act or the proposed amending Act or Regulations upon the partnership agreement, he shall have the right to proceed to arbitration to have the question of hardship determined

(b) Where the parties so agree the question will be referred to a single arbitrator nominated by or on behalf of the partners

(c) Where the parties do not so agree the question will be referred to a Committee of Arbitration consisting of a chairman with legal qualifications and a qualified accountant, both nominated by the Minister, and a medical practitioner who is or has been in general practice nominated by the President of the British Medical Association

(d) It is recommended that the agreed arbitrator or the Committee of Arbitration should be empowered

(i) To modify the terms of an existing partnership agreement and to modify the application thereto of the Act or of the proposed amending Act or Regulations in any manner which he or the Committee thinks equitable for removing or preventing hardship

(ii) To direct the payment or repayment of money but not to increase or diminish the aggregate compensation attributable to the partners in accordance with the terms of the agreement as they existed at the appointed day

(iii) To recommend that an existing partnership should be dissolved. This recommendation will be evidence\* that dissolution is a just and equitable solution in any proceedings by a partner for the dissolution of the partnership instituted within, say, three months of the arbitration award

A partner who has not submitted his hardship claim to arbitration will be precluded from relying on such hardship as a ground for dissolution of the partnership by the Court under the Partnership Act, 1890

### New Appointed Day for Entry to Service for Members of Existing Partnerships

9 Having regard to the difficulties which arose about the interpretation of the Act, the Committee considers that it would be fair that every member of a partnership existing at the appointed day should be allowed a short period after the coming into operation of any amending Act during which he may, after considering his position in the light of its terms, apply to be included in a medical list on the same terms as would have applied had he done so before the appointed day

It is recommended that a partner who makes application within a period prescribed and in the manner specified by the amending Act shall be entitled to be included in the medical list of the executive council for any area in which he practises and for the purposes of Sections 34 and 36 of the Act shall be deemed to have made such application before the appointed day and to be and always to have been an 'inside' partner

In effect this means that a partner entering the Service before the new appointed day will have the right to be included in the list of the area(s) in which he is practising, whatever the views of the executive council or the medical practices committee as to the medical needs of the area and will qualify for compensation as if he had joined the Service before July 5, 1948

This recommendation justifies and meets one of the main criticisms of the Negotiating Committee—that members of partnerships had a right to know before the appointed day how the Act would affect them. Only those who entered the Service by July 5, 1948 were entitled to compensation yet the Minister expected members of partnerships to decide whether or not to enter the Service without knowing whether in fact the rights and obligations in partnership deeds were nullified by the Act

\*The recommendation will be prima facie evidence if made by a single arbitrator and conclusive evidence if made by the Committee of Arbitration

### Changes of Status after the New Appointed Day

10 There remains to be dealt with the position of a partner who enters the Service for the first time after the new appointed day to which reference has been made in the last paragraph. For convenience this partner, who up to the present has been referred to as an 'outside' partner, is referred to by the committee as a 'new listed' partner. The committee recommends

1 That where an 'inside' partner has an obligation or option to purchase the share of a 'new listed' partner the contract shall remain in full force subject only to the modification that the purchase price shall be either the contract price or the compensation payable from the Supplementary Compensation Fund, whichever is the less

This differs from the recommendation applicable to the purchase by an 'inside' partner of a share from an 'outside' partner (paragraph 7 (iv)), in which case the 'inside' partner remains bound to pay the contract price—which may be more or less than compensation—receiving from the Supplementary Compensation Fund a compensation payment not exceeding the contract price

2 That where an 'outside' partner has an obligation to purchase the share of a 'new listed' partner the obligation shall be converted into an option, where there is an option to the same effect it should remain unaffected. If the option is exercised the contract price shall be payable

The same conditions are to apply when a 'new listed' partner has an obligation or option to purchase the share of another 'new listed' partner

3 That where a 'new listed' partner has an obligation or option to purchase the share of an 'inside' partner he should receive a free transfer on the same principles as those set out in paragraph 6, the compensation due on that share becoming immediately payable to the 'inside' partner

4 That where a 'new listed' partner has an obligation or option to purchase the share of an 'outside' partner the contract shall remain in full force and effect

### Partnerships Other than Service or Mixed Partnerships

11 In the case of a partnership existing at the appointed day none of whose members was on that date or on the new appointed day on an executive council list but one of whose names is included in such a list after the new appointed day the Committee recommends that the provisions of the partnership agreement shall remain in full force except that any obligation to purchase the share of a partner who has joined the Service shall be converted into an option

### An Inside Partner Who Ceases to be Included in a Medical List

12 Where the name of an 'inside' partner ceases to be included in an executive council list the Committee recommends that his position shall remain unaltered in relation to purchase obligations and options in the partnership agreement except that after his name ceases to be on an executive council list he shall not become entitled to compensation out of the Supplementary Compensation Fund

## FREE HOSPITAL PLAN IN TRANSVAAL DISPUTE SETTLED

By the Public Hospitals Ordinance (Transvaal), 1946 the Provincial Council wished to provide free hospital treatment to all members of the community, including out patients and patients attending detached clinics. The three Transvaal branches of the Medical Association of South Africa opposed the Ordinance and their hand was strengthened by very large votes against it in a plebiscite held among medical practitioners (Supplement Sept 18, p 123). The dispute has now been settled and full hospital services have been restored. The agreement provides that patients unable to pay for medical services will receive free medical and hospital treatment at public hospitals. Others well able to pay must get the services of their own private doctors, except for such medical services as are available only in the public hospital services, when they will be given free of charge

Amending legislation will be introduced forthwith to meet the terms of the agreement. It will include provisions to enable a patient who is dissatisfied with the decision on his ability to pay to appeal to the Hospital Board, whose decision will be final

For topical application in  
allergic dermatoses . . .

## 'Benadryl' Cream

'Benadryl' the potent antihistamine agent, is now available for topical application as a cream containing 2 per cent of the drug in a specially prepared water miscible base

'Benadryl' Cream is used either alone or to supplement oral or parenteral therapy. In the treatment of atopic or contact dermatitis and erythema multiforme it has additional value as a local anti pruritic, reducing the erythema oedema and pruritus met with in these conditions

'Benadryl' Cream has also been found to be of benefit in the treatment of some cases of pruritus ani, pruritus vulvae, neuro dermatitis, bee stings and insect bites

It is available in 1 oz collapsible tubes

THE SPECIFIC AGENT  
AGAINST GRAM-NEGATIVE  
ORGANISMS

**PHENOXYETOL**  
NIPA

Phenoxyetol is effective against Penicillin resistant organisms and compatible with Penicillin.

Phenoxyetol is not inactivated in the presence of serum

Phenoxyetol is especially effective against gram-negative organisms including *Ps. pyocyanea*. It is used by local application in the treatment of infected wounds, abscesses, indolent ulcers associated with *Ps. pyocyanea*.

Phenoxyetol is very effective in pyocyanea infections of burns or superficial wounds. It is especially useful in the preparation of surfaces for skin grafting associated with *Ps. pyocyanea*, and may also be used together with Penicillin in solutions and creams.

Phenoxyetol should not be used for parenteral injection

## CONFERENCE OF LOCAL MEDICAL COMMITTEES

### REMUNERATION OF PRACTITIONERS

The Annual Conference of Local Medical Committees, summoned by the Insurance Acts Committee, was held in the Great Hall of B.M.A. House, London, on Thursday, Nov 25, under the chairmanship of Dr J A BROWN (Birmingham). The main document before the Conference was the report of the Insurance Acts Committee (*Supplement* Oct 16, p 135), to which was appended a report of matters dealt with by the General Practices Subcommittee of the Negotiating Committee.

Certain proposals for the rectification and improvement of the representation and procedure of the Conference were made and remitted to the new committee.

After a motion by Dr J G THWAITES (Brighton) criticizing the arrangements for publishing the agenda had been moved, it was agreed that in future the agenda should be published in advance and circulated to members of local medical committees.

#### The Organization of Practitioners

Dr E A GREGG (chairman of the Insurance Acts Committee) moved that the annual report be received, and also moved approval of the proposal to rename the I.A.C. the 'General Medical Services Committee' and leave unchanged, at the outset, the constitution of the new committee.

Dr A W GARDNER (East Sussex) moved that the General Medical Services Committee be requested to review the mode of election and representation to the committee and to report thereon.

Dr GREGG said that the new committee would review the whole representation and bring forward a report to the Conference.

Dr S JOHNSTON (Halifax) moved that the new committee be constituted to form the executive body of all general practitioners grouped within the framework of the B.M.A. into areas corresponding to B.M.A. Divisions, that representatives should be elected directly by votes of practitioners each constituency corresponding to the area of each Branch Council, and also by the Central Conference, further that the Executive Body should be subject to no other body by veto or otherwise in matters which had been decided by a Central Conference, and that the committee should have direct access to the Minister of Health.

Dr J A PRIORHAM hoped the Conference would not pass this resolution. The way the old I.A.C. was elected was a better way and gave a fully representative committee.

Dr F M ROSE (Preston) said that their organization had been built up from the unit which was the Local Medical Committee. The I.A.C. in the past had been subject to no other body and the same would be true of the new committee.

Dr GREGG hoped that they would not lightly break up the old arrangement. The old Panel Committees were units which had the advantage of regular meetings and accumulated experience, and one of the characteristics of the I.A.C. had always been that each member of the committee was a person of sound knowledge and experience of the matters with which he had to deal.

Dr JOHNSTON replied that his criticism was not directed against the I.A.C., but now that they were in a national service they should be organized in some manner which would ensure that the Minister could have no possible jurisdiction over them.

It was agreed to refer the whole question to the General Medical Services Committee.

Dr A W GARDNER (East Sussex) moved that the committee should state fully the scope of its ability to protect general practitioners in the N.H.S.

Dr WAND proposed that this and other resolutions dealing with the question of organization should be referred to the committee.

This was seconded by Dr J A IRELAND and agreed to.

The proposal that the new committee be called the General Medical Services Committee was also agreed.

#### Remuneration

Dr GREGG moved approval of the parts of the report dealing with remuneration.

Dr J B MARSHALL (Kent and Canterbury) moved the following resolution.

"That this Conference considers (1) the present capitation fee of 18s to be grossly inadequate in that

(a) the amount of work imposed upon the doctor by the inclusion of the whole population instead of the workers only has been very greatly increased, and

(b) whilst in certain parts of the country the doctor's financial position may have improved there remain very large areas in which his income has been halved or even further reduced,

and calls upon the General Medical Services Committee, as a matter of the utmost urgency, to take all possible action to secure an adequate over-all increase in order to relieve the serious hardship resulting from the new Service."

He had taken a census of his own practice, which was a rural one, and had asked other doctors to do the same. From July to October, 1948, there had been a 34% increase in visiting as compared with the corresponding period last year. The population of Kent was 1,458,000, the number of persons on doctors' lists was 1,373,000, and the doctors taking part in the Service, including 9 assistants numbered 667. Out of 600 doctors, 102 had lists of over 3,000, and 72 of these had lists of over 4,000, but the average number of patients per doctor in Kent was 1,660, and the income for 5/6ths of the doctors worked out at an average of only £1,500. He urged that there must be an increase in the capitation fee so that doctors with small lists could receive an economic remuneration, or else the capitation fee for the first 1,000 or 2,000 on the list should be made very much higher.

Dr R W COCKSHUT moved to substitute the word "immediate" for "all possible" in the Kent resolution. It would be found that some members of the profession could not keep body and soul together and large numbers would be found pressing for the basic salary, not because they agreed with the principle of it, but because it was necessary for the support of their families. At the root of their difficulties was the rate of pay. The capitation fee was inadequate. He was profoundly distressed by what was happening in Middlesex to-day. There were just over 1,500 patients for each doctor in the Service. He instanced the case of Willesden, where there were 186,000 people with 210 doctors. It was quite impossible to implement the Service in Middlesex at a capitation fee of less than 30s a year. That was the first thing they had to go for—an adequate capitation fee—and that must be obtained immediately. There would have to be some redistribution of doctors, and the Government must finance such distribution by making up the loss that some men had suffered.

Dr N E WATERFIELD (Surrey) gave statistics collected from about 20 doctors in varying semi-rural areas of his county. These figures indicated the serious losses which Surrey doctors were suffering. There were 800 doctors in Surrey and 1,300,000 patients. A little calculation showed that it was impossible for many of these 800 doctors to make anything like a reasonable living. When one deducted people who had got a full list there was not the number of patients in Surrey to give an average of more than 1,200. Obviously later on there would be a certain readjustment, and wherever a doctor dropped out the General Practices Committee was being told that there was no need to replace him.

Dr W F HUDSON (Oxfordshire) said that general practitioners, particularly in rural and semi-rural areas had had a very raw deal, and unless immediate action was taken the matter would go from bad to worse. The global sum was not only inadequate in amount but unfair in operation. The general practitioner was tied down to a quite inadequate figure. The basic salary took on an entirely new aspect when the giving of it meant taking it away from one's fellows' remuneration.

Dr T O JONES (Denbigh and Flint) said that in his area the average number of persons on doctors' lists was just over 1,400. There was a large coastal belt with a great many chronic sick and there were some doctors who had only about 700 on their lists. They had previously been making a good income, but now their incomes were very small indeed. One would like to shake the complacency out of the Ministry of Health. Whenever this question was referred to, the Ministry spoke of lists of 4,000 and the man who had got a list of only 1,000 was disregarded.

Dr S JOHNSTON (Halifax) said that in asking for an adequate capitation fee they were doing no more than demanding the implementation of the promise which was given them.

before this Service was inaugurated. Very few doctors could achieve 4,000 on their list and surely 4,000 was an almost impossible figure. What they had to do was to go all out for a bigger capitation fee.

#### STATEMENT BY CHAIRMAN OF COUNCIL

Dr H GUY DAIN (Chairman of Council) speaking on the motion by Kent and Canterbury that the Conference considered the present capitation fee to be grossly inadequate said that it had been obvious that this particular motion would be an important one in to-day's proceedings. "That brings immediately to the surface the difficulties that we are in in these early days. We have two difficulties—namely, the demands on the doctors made by the patients, and the insufficient pay for the doctors for the demands made upon them. The fact that we have these two difficulties, I hope, will not prevent us from doing—as we have undertaken to do—our utmost to make the Service satisfactory." It was interesting that that morning there had been no suggestion of interference with their clinical freedom.

If the profession had not taken its stand there would now have been a vast impairment of the doctors' freedom. We have attained clinical freedom, freedom of speech, freedom of choice both ways, for patients and doctors, and freedom to do private as well as State work. We are free to regulate our lists, we need not take more than we like, and we can practise where we like if the area has not been declared an over-doctored one. We have attained in this framework of the new Service a definite position of freedom very fairly established. It is for us to see that it is maintained. There is a new organization called the Fellowship for Freedom in Medicine, and if they can assist us in any way to maintain the freedom we have got we shall be only too glad of their help.

I have said all this because it may possibly not be given full value. We want of course, and must have the full support of the doctors in the Service in any action that may require to be taken. Because we are in a difficulty over basic salary we must not go back on our principles that we are opposed to a basis of salary altogether. We have always been in favour of free enterprise. Doctors in one area after another are asking to have areas closed. We are against the principle of closed areas and I hope we shall not spoil our position in the Service by demanding the closure of areas. But there would be fewer requests for closed areas if we were getting enough money. We warned the Government beforehand that there was not the man power in the medical profession or the nursing profession nor the hospital beds available to implement this Service. Our warning was not heeded and now we are reaping the unfortunate consequences.

It was not difficult to foresee the extra work which would fall upon the doctor. It would be a strange mother nowadays who when the doctor was in attendance did not ask him to look at other members of her family. It is now a question not of visiting a patient but of visiting a family. It is overwhelming us and in the forthcoming winter may cause a complete breakdown of the whole Service. (Hear hear.)

'On the question of pay, not only is the capitation fee insufficient but it is not properly distributed. We should insist that any doctor who can show that he is suffering hardship or even serious diminution of income should have an immediate claim to be paid out of special funds. Such doctors should not be penalized because the Service is not yet properly constructed or its financial side. We have put it to the Ministry that the Special Inducements Fund should be immediately opened and payment should be made to any doctor who can show that he is suffering serious diminution of income.'

"On this question of diminution of income I think that many doctors do fear a greater diminution than may in fact be found at the end of twelve months. If proper payments are made it will not be the fact that your first quarterly payment multiplied by four will be your income for this year. We are investigating methods by which a doctor can be paid so that we shall be able to form some idea of the total sum available for all doctors. The capitation fee must be reassessed in order to make certain that it implements the Spens recommendations and we must have a large percentage for the alteration in value. The betterment factor of 20% is a thing that has most obviously spoiled the present position. The 'Whitley' machinery shortly to be

established will have before it all the facts we can accumulate on the way in which this payment question is working and a claim will be made for an increase. (Applause.) We are now in the position that we are no longer handicapped by the fear that we may lose our compensation, and if we do not get satisfaction quickly it will not be beyond the bounds of possibility to withdraw our services, not entirely because we are not getting enough money, but because under the conditions obtaining we cannot properly deliver the goods. (Applause.)

#### Demand for Capitation Increase

Dr J A PRIDHAM (Dorset) hoped that the committee would press for the distribution of the Inducement Fund and the removal of the ceiling of £400,000.

Dr FRANK GRAY (London) moved to delete from the resolution the stated grounds for the inadequacy of the fee so that it became a straightforward demand for an increase. Before the war there was a good deal of argument about the number of services rendered and their relation to remuneration but later they had the Spens Report with its entirely different approach—namely that of a fair remuneration for the profession as a whole and a proper distribution of that remuneration. There was now proceeding in a large area a detailed inquiry into whether or not the findings of the Spens Report had been implemented. If it was found—as it almost certainly would be found—that they had not, it would furnish the strongest possible case for going forward to the Ministry.

Dr GREGG said that the ground had been broken with the Ministry the previous week. In view of reports from all over the country they could not wait for further details before putting forward a claim for improvement in remuneration, and it was essential to draw the attention of the Ministry at once to the existing conditions. In rural, semi rural, suburban, and certain special areas doctors had realized their incomes were vanishing. In many such areas it was impossible to have a list which would enable the doctor to maintain his previous economic position. All this had been laid before the Ministry. One outstanding point was that there should be an immediate use of the Special Inducements Fund that there should be no attempt to divide it, looking forward to future commitments but that full and immediate help should be given to the doctors concerned, and that they should be encouraged in every way to make application for such increases in remuneration as their present position justified.

On the question of mileage rural practitioners were entitled to a much more generous interpretation of the mileage payments. As to the basic salary they were against it in principle, though they understood the importance of it in some cases. The matter was causing much heartburning. It meant taking money from those with diminished incomes in order to give it to others. This 18s capitation fee was a delusion, it was 18s and then so many things were clipped from it. They had told the Minister they had got to get down to a capitation fee they could understand. He asked the Conference to contemplate quite seriously the position that had been described by some speakers already. It was quite possible that as they went into this question of remuneration they might have to tell the Ministry that if there was not a satisfactory improvement the question of refusing to continue to work in the Service must be put to the profession. (Hear hear.)

The global sum had been based on 17,900 practitioners participating in the Service. The actual number to-day was about 19,400 and financial provision must be made in proportion to that increase.

Dr H H GOODMAN (Newcastle upon Tyne) said that to-day the income of doctors bore no relation to the work they were doing. To resort to the Inducements Fund was not sufficient; they must get down to the capitation fee.

Dr SMITH POOL (Glasgow) said that the failure to implement the Spens findings was the crux of the difficulty.

Dr A M WESTON (Dudley) considered that the Inducements Fund was a form of charity which none of them should be prepared to accept.

The Canterbury and Kent motion, the phrasing of which had been amended in various respects, was carried unanimously in the following form:

"That this Conference considers the present capitation fee to be grossly inadequate, and calls upon the General Medical Services Committee, as a matter of the utmost urgency, to take immediate action to secure an adequate over all increase in order to relieve the serious hardship resulting from the new Service."

Dr J B MARSHALL (Kent and Canterbury) further moved That, concurrently with an adequate increase in the capitation fee, the upper limit of patients should be drastically reduced

Dr R W COCKSHUT considered that this was one of the remedies for relieving symptoms which would do more harm than good. They had no mandate to interfere with the free choice of doctor. It would introduce a levelling which would pave the way to a salaried service, and it would not deal with the real problem, which was the capitation fee.

Dr W D STEEL (Worcester) suggested that this point be referred to the new committee.

Dr GREGG accepted the reference.

It was agreed to refer the motion to the committee.

Dr J A IRELAND then moved that the whole of the remaining motions on remuneration be similarly referred to the committee for sympathetic action.

This was agreed to.

A separate motion by Dr C W MARSHALL (Exeter) calling for an increased capitation fee in the case of children under 14 and adults over 65 was lost.

### Mileage

Dr W FRASER (Cumberland) moved

That the Conference views with alarm the straitened financial circumstances of many rural practitioners, as a result of the present totally inadequate mileage payment, which in no way covers the cost of motoring, and urges the General Medical Services Committee to press for an immediate upward revision which will meet the needs of those concerned.

Mileage payment had sometimes been spoken of as 'income'. It was not income at all, but a practice expense and in rural practice a very heavy one. Another consideration was the time factor.

Dr R ROSE (Berkshire) said that rural practitioners could not possibly reach what to town doctors would be considered an adequate number on the list. Dr A C MACDONALD (Banff, Moray, and Nairn) said that the mileage fund should be entirely separate from the capitation fee.

Dr GREGG said that the Conference had agreed that morning to a broad general statement that the capitation fee was inadequate. The mileage fund even now was also inadequate. Therefore it would be wise to pass a resolution to that effect in order to strengthen the hands of those who had to negotiate this matter with the Ministry. He hoped that throughout the country there would be applications for a share in the Inducements Fund, which was not a charity, but a right.

The motion was carried.

Dr J E RUSBY (Leeds) moved that payment for mileage should not be a deduction from the Central Practitioners Fund, but should be provided from a separate fund.

This was supported by Dr A BEAUCHAMP (Birmingham). Dr J O McDONAGH (Perth) said they had always been dissatisfied with the amount received by way of mileage grant, particularly taking into consideration the time factor. But even if they did succeed in getting higher payment for mileage they would, as matters now stood, only be taking something out of the general pool. Dr J C PEARCE (Norfolk) said that the Rural Practitioners Subcommittee wanted to obtain figures from rural practitioners as to their running costs and mileage covered.

The motion was carried.

### Certification

A motion by Kent and Canterbury asked the Conference to declare that the requirement of Section 33 (2) (d) of the National Health Service Act to make a free issue of a wide variety of certificates was unjust, and to request the committee to take all possible steps to secure its withdrawal and to arrange for the payment of an adequate standard fee for all such certificates in the case of statutory notification of infectious diseases.

Dr S WAND (Birmingham) said that a year or two ago the Association set up a Certification Committee, of which he was chairman, and evidence was prepared for submission to a departmental committee. That evidence was brought in summary before the Annual Representative Meeting and, with some amendments, approved. It was to be presented on Dec 15. The question of the adequacy of the standard fee for certificates would depend upon the results of their deliberations, but

the idea that was before the Association committee was to eliminate as many certificates as possible, leaving a few 'omnibus' forms.

It was agreed to refer all the resolutions on this subject to the General Medical Services Committee, with the assurance that they had received or would receive the attention of the Certification Committee.

### Expenses of Local Medical Committees

Dr C H STEWART-HESS (Wallasey) moved that in view of the wider functions of local medical committees (including statutory obligations with regard to over prescribing and record keeping) the expenses of these committees should be borne by the Ministry and not by individual practitioners.

After Drs D F HUTCHINSON, A W GARDNER, J O McDONAGH and F E GOULD had spoken, Dr J A IRELAND (Shropshire) proposed a rider to the Wallasey resolution, but that a voluntary levy fund be also set up for disposal by the local medical committee.

Dr GREGG hoped they would throw the resolution out and the rider too.

The Wallasey motion and the rider were rejected 'almost unanimously'.

Dr D C WILSON (Inverness) moved that the expenses of members attending local medical committees should be met by a statutory payment from Government funds and should not be borne by the local practitioners' pool. The total expenses in travel each time a meeting was held were between £55 and £60.

Dr GREGG accepted the reference of the matter to his committee.

### Basic Salary

Dr A H JACK (Eastbourne) moved that in the amending Bill it should be enacted that all basic salaries should be drawn from a separate central pool created for the purpose and not from local pools.

Dr HOWIE WOOD (Isle of Wight) spoke of the difficulty of resisting claims for basic salary because the applicants put forward good grounds for the concession in almost every instance.

Dr F GRAY (London) said that this was one of the most difficult questions with which they had to deal. They had already agreed that the most important thing was to ensure that the central practitioners' pool was adequate. Basic salary might be paid (1) out of the local practitioners' pool, (2) out of the central practitioners' pool, or (3) out of a separate fund if one could be created. But supposing a proposal for the creation of a separate central fund were made, was it not likely that the Ministry would say, "This is part of the remuneration going to practitioners," and that that factor would be taken into account in dealing with any claim that the practitioners' central fund should be increased? In fact it would be impossible to create a separate fund. But if they went to the Ministry and said, "This is a difficult and arduous and unfortunate business, will you take it over from us and do it for us?" no doubt the Ministry would very readily do that and distribute basic salaries very widely indeed, for it was the Ministry's policy to have the basic salary established. In his view the profession should not shirk the task because it was unpleasant or arduous. The profession had been given certain powers in the present set-up and power always entailed responsibility. Harm would be done to the profession if it were said, "We do not want this power and this responsibility, we want to hand it over to somebody else." How could any body of doctors know whether the cases put before it were sound if such cases came to them from all over the country and they were unaware of the details of the local area? He believed it was right that this should be a charge on their funds. Those assembled in that Conference were by the nature of things experienced practitioners, and they had to consider the position of young practitioners who had been promised so many things by the Minister but in fact had had a raw deal. These young practitioners were told that they would not have to buy a practice, but the Minister had made it almost impossible for them to get a practice. It was part of the duty of the profession to undertake these payments in a spirit of fairness, and they should shoulder their responsibilities themselves and not seek to put them on to somebody else. (Applause)

Dr J T McCUTCHEON (Glasgow) felt that means should be found of establishing a fund for fixed annual payments from a source separate from central and local pools

Dr H H GOODMAN said that he was afraid this question of basic salary was going to split the profession

Dr GREGG said that he found it very difficult to answer Dr Grays speech. It was true that the effect of this basic salary was very bad for the whole profession and was tending to create cleavage. But he could see that a solution which was obtained by handing the matter over to the Minister was likely to create probably an even more serious position. The Ministry would be pleased to have an opportunity to hand out basic salaries all round and to go back on the position reached when they got away from universal basic salary. One of the worst points about the present position was that there was an appeal to the Minister who could grant appeals and hand out money that was not his money. The best solution might be to press that these appeals be determined by a professional body.

It was agreed to refer the whole matter to the committee in the light of the discussion.

Dr R W COCKSHUT urged that they endorse what Dr Gregg had stated. Let them keep their eyes fixed on the capitation fee and all other things would be added unto them.

On the motion of Dr GRAY all the motions on the agenda dealing with basic salary—some twelve of them—were referred to the committee.

### Elections

Dr Brown had intimated that he could not allow his name to go forward again for the Chairmanship of the Conference, and on a ballot Dr Walter Jope (Blantyre Lanarkshire) was elected.

The following were elected by the Conference to the General Medical Services Committee: Dr A Beauchamp, Dr J A Brown, Dr I G Innes, Dr J A Ireland, Dr J A Pridham, and Dr F M Rose.

### Specialist Services

It was agreed on a motion by Worcester that in the event of the Ministry agreeing to payment for performance of services of a specialist character by general practitioners, the remuneration therefor should not be a charge on the Practitioners' Fund.

Dr E L K SARGENT (Surrey) moved

'That it is essential, in the interest of medicine, that some degree of specialization in general practice should be encouraged and provision made for it, and in particular, that the General Medical Services Committee be urged to continue to press the Minister in order to secure his recognition of specialist services by general practitioners such as were dealt with under National Health Insurance by means of form GP 45.'

Dr HOWIT WOOD (Isle of Wight) spoke in support of the motion. The position of the part time general practitioner specialist was far from secure.

Dr J C PEARCE (Norfolk) said that one of the difficulties which they were up against here was the regional hospital board.

Dr W H HAYES (Bristol) said that if these general practitioner specialists were withdrawn and all the work they had to do fell upon full time specialists, the full time specialist service already strained, would break down immediately.

The Surrey motion was carried.

A motion by Walsall was agreed to that a special fee of £1 should be payable to medical practitioners for attendance in emergency for the arrest of haemorrhage after dental extractions and that this payment should be made from the same source as dental payments for the same service.

A motion by Perth was also agreed to that in addition to the fee for the administration of an anaesthetic for a dental operation an agreed mileage fee should be payable.

### Maternity Medical Services

A motion by Bath was agreed to that in the case of obstetric emergencies the general practitioner should be allowed to call in an obstetric specialist under the Act for patients in private nursing homes as he would for domiciliary visits in the patients' own homes.

Dr K J T WILSON (Dorset) moved

That this Conference considers that the continuing experience of general practitioner-obstetricians is in the public interest and there-

fore asks the General Medical Services Committee to oppose vigorously the exclusion of these practitioners from attendance on patients in maternity beds that are administered by Regional Hospital Boards.

He said that social conditions had driven women more and more into institutions for their confinements, and many beds formerly available to private practitioners had been taken over by Regional Boards, the work being done by an obstetric specialist or by the house surgeon or midwife with the specialist somewhere in the background.

The motion was carried.

Dr D SAKLATVALA (West Bromwich) moved that the payment of a fee for maternity medical services should not be made dependent upon the carrying out of any examination on a particular date. He said that it was right to make some effort to have this examination carried out on the date stated but the fee should not be conditional upon such a requirement.

The motion was agreed to.

Dr D H A GALBRAITH (Cornwall) had a motion urging that the obstetric fee should be subject to some extra allowance in rural areas in view of the distances to be travelled. The ordinary mileage payment did not meet the case, and some special arrangement should be made in rural cases.

This also was agreed to.

A further motion by the Isle of Wight was also agreed to, expressing the opinion that clerks of executive councils should when payments were made give details as to how maternity fees were made up.

A motion by Surrey, that a medical record card should be provided for the use of practitioners on the obstetric list in respect of patients accepted for maternity medical services, was referred to the committee.

### Provision of Medicines for Private Patients

A motion by Kent and Canterbury was proposed in the following terms:

'That this Conference is of opinion that in the public interest private patients should be entitled to receive any drugs and prescribed appliances necessary for their proper treatment at the cost of the Service.'

Dr H H GOODMAN (Newcastle upon-Tyne) said that a couple of years ago the Minister said in Parliament that any patient could avail himself of the whole Service or of any part of it. The speaker took 'any part of it' to include pharmaceutical benefits. Many patients were prepared to pay for the personal services of their family doctor but were not able or willing to pay for impersonal services such as the pharmaceutical benefits. The position might be met if some patient issued a writ against the Government with a view to ascertaining the legal position of the private patient in this respect under the Act.

The CHAIRMAN hoped it would be borne in mind in considering this matter that it was the public interest they were seeking and not private interest.

Dr H H D SUTHERLAND (London) said that the other side of the picture had not been stressed. Apart from the economic pressure put upon certain sections of the public to compel doctors to take them as public patients, the difficulty was that many patients would say to their doctor, 'I can afford your fees, but I cannot afford the drugs.'

Dr J A IRELAND drew attention regretfully, to the provision of Section 38 of the Act, and said that he was afraid the Minister was covered by the Act.

The motion by Kent and Canterbury was carried unanimously.

### Superannuation

Dr R ROSE (Berkshire) moved to ask the committee to investigate the 35% and 50% respectively allowed for practice and mileage expenses and to endeavour to see that both these percentages were raised before further deductions were made towards the Superannuation Fund. He said that this motion had been put down for the purpose of promoting discussion.

Dr GREGG pointed out that superannuation was on net income. The higher the practice expenses the lower would be the superannuation. The Berkshire resolution was an example of a motion which had not been sufficiently thought about.

Dr A W WESTON (Dudley) considered that the figure to be taken for expenses should be the figure which the Inland

Revenue would allow one to charge. He did not know any practice where 35% expenses would be allowed by the Inland Revenue.

Dr S WAND said that if the expenses were fixed at a higher rate than 35% superannuation would be reduced. The superannuation scheme as it stood was a very good one. In addition to what was contributed by members of the profession a contribution was made by the Government. The suggestion that it should be based on income tax returns was just fantastic because it meant that superannuation arrangements and deductions would have to be made for each individual practice. He asked the Conference to leave this matter alone.

It was agreed to pass to the next business.

The Conference agreed without discussion to a motion by Middlesex deploring the addition of foreign visitors to the population at risk without any additional payment being made into the central fund to cover their treatment while temporary residents in this country. The committee was urged to continue to press the Minister to take action in this matter.

### Vaccination

Dr A B DAVIES (Walsall) moved

"That vaccination and immunization carried out under Section 26 of the Act shall carry a proper fee for work done."

It had been their experience in Walsall that the local authority had refused to shoulder responsibility for vaccination for all cases apart from infants. This was entirely opposed to the sense of Section 26 of the Act to the statement (Section 86) in the White Paper, and also to the instruction given local authorities in Circular 66. Unless there was some definite arrangement about vaccination and the local authority did shoulder responsibility it would mean that once again the general practitioner would be doing the job without receiving any payment.

Dr WAND said that in the discussions it was understood that vaccination and immunization would be carried out by general practitioners and that some suitable fee would be arranged. Practitioners had been encouraged by local authorities to carry out diphtheria immunization. A conference was held at the Ministry a few weeks ago, and the sum of 2s 6d was offered for the purely clerical work of filling in a form. This was refused out of hand, and it was insisted that the work carried out under Section 26 of the Act should carry an appropriate fee. The Association Committee which had been dealing with this matter had made its own assessment of the value of vaccination and immunization and the payment for the liability of the practitioner for carrying out these services. He asked the Conference to pass the Walsall resolution and to be a little patient with the committee because it had not so far had a reply to its representations.

The resolution was carried.

### Domiciliary Consultations

Dr F E GOULD (Birmingham) moved

"That this Conference strongly objects to any method of obtaining the services of a consultant for a domiciliary consultation which interferes with the normal personal relationship between a general practitioner and a consultant."

He produced an instruction from the Birmingham Regional Hospital Board to a hospital management committee. The question at issue was the formation of a consultants bureau, that is to say, a bureau to deal with requests from general practitioners for domiciliary visits to patients. He himself was not concerned with the rights or wrongs of such a bureau, but he objected to the following paragraph: "Each specialist named will be on a list under the bureau and the services of any particular specialist will be obtainable through that bureau only." That was a gross interference with the liberty of the general practitioner and had impaired his previous happy relationship with the consultants. He added that the matter was to be brought before the Central Consultants and Specialists Committee.

Dr GREGG said that it might be desirable to hear what their consultant friends had to say on this matter before proceeding any further. He asked that this be left in the hands of the committee, which would take the opportunity of obtaining the consultants' views.

It was agreed to leave it to the General Medical Services Committee on this understanding.

### Treatment of Private Patients at Health Centres

Dr D F WHITAKER (Surrey) moved

"That provision should be made for the treatment of private patients in health centres."

The Minister had said that private patients would not be treated in health centres. This would mean that a doctor would have to have two centres for consultation, one for his private and the other for his public patients.

Dr A BEAUCHAMP (Birmingham) said that they wanted the private patient to go to the health centre if he so desired.

Dr GREGG said that it might be wise for the committee to look into the matter again.

It was agreed to pass to the next business.

### Other Motions

Dr KENNEDY (Isle of Wight) asked the Conference to express the opinion that the Ministry should be responsible for the provision of suitable locumtenents for practitioners while away on holiday, and for the payment of the fees of the locumtenent and his maintenance and support.

Dr GREGG said that he hoped they were not going to slip into the position of handing over to the Ministry all sorts of things which concerned themselves.

The Isle of Wight motion was lost.

On a motion by Middlesex supported by Lancashire, the Conference expressed the view that practitioners should have direct access for their own patients to the x-ray and pathological departments of hospitals.

Dr GREGG made a brief statement on the report, just issued, of the Legal Committee on Partnerships. The report completely justified all the criticisms the profession had made. There was good reason to be satisfied with the action taken in this matter.

The Conference adopted a motion by Staffordshire expressing 'regret and dismay' that practitioners not participating in the National Health Service had been excluded from rendering service, as they had done in the past, to their own patients in local cottage hospitals. The mover, Dr R W RAR, said that in one cottage hospital in his area two doctors who had not entered the Service had been regrettably refused the hospital. Dr GREGG said that if detailed information were given the committee would take up the matter directly with the Ministry.

A few motions remained on the agenda, but the Conference having already sat from 10 a.m. to 6.45 p.m. it was decided to refer them for sympathetic consideration to the new committee.

### CONFERENCE DINNER

At the close of the Conference the representatives dined together under the chairmanship of Dr J A Brown. The health of the Insurance Acts Committee was proposed by Dr A W Weston, of Dudley, who spoke in particular of Dr Gregg's ten-year record as chairman. Dr Brown also paid a tribute to Dr Gregg, saying that both in the chair of the committee and in negotiations with the Ministry he had shown outstanding quality. Dr Gregg in response said that there was a certain sadness in the present occasion, for the organization which had taken shape shortly after the introduction of National Health Insurance had now reached the end of its existence. No other body associated with the profession deserved greater praise than the Insurance Acts Committee, which had sustained the position of the insurance practitioner over a period of some 35 years. He himself became a member of the committee about 1920, and had been its chairman since 1938. It had been a wonderful experience and training, and he had learned the mind of the general practitioner as he could have done in no other way. The General Medical Services Committee was now in the shaping and he was sure that it would prove as capable of looking after the interests of practitioners as the old 'IAC' had been. Dr Gregg concluded with an appeal on behalf of the Dan Fund for the education of the children of doctors in needy circumstances. A collection taken at the tables resulted in the record sum of £158 10s.

Dr Walter Jope, chastened by the thought that he was to be his successor, proposed the health of Dr Brown on his

retirement from the chair of the Conference after holding the position for five years. Dr Brown, in reply said that his work had been a labour of love, and he praised the work of the secretarial staff at B M A House. Dr Hill, on behalf of the recipients of basic salaries, from central, not local, funds' made a brief response to which Dr Stephenson, Deputy Secretary, who will be in charge of the new General Medical Services Committee added a few graceful words.

## REMANDS FOR EXAMINATION OF CERTAIN OFFENDERS

The Committee on Psychiatry and the Law recommends increased use of the power to remand for the examination of certain offenders after conviction but before sentence. The Committee which is a Joint Committee of the Association and the Magistrates Association, has been studying the Criminal Justice Act, 1948, and is anxious that the best results shall be derived from those sections which provide for the mental and physical examination of certain offenders. The Lord Chancellor and the Home Secretary have been informed that in the Association's opinion the best results will not be gained from these sections of the Act unless all magistrate's courts and Courts of Quarter Sessions grant to such offenders, after the finding of guilt and before passing sentence, a remand long enough to permit the necessary social and medical examination to be carried out in the full knowledge of the decision of the court on the facts. The Council of the B M A has suggested that the arrangements of the work of a court should be altered, where necessary, to make such remands possible.

## Questions Answered

### Maternity Medical Service

**Q**—What number of antenatal examinations are required to enable a fee to be claimed under the maternity medical service arrangements and what fees are payable?

**A**—The maternity arrangements cover antenatal care throughout pregnancy (including the initial antenatal examination and one at the 36th week), attendance at the confinement if the doctor thinks it necessary or he is called in by the midwife, attendance during the puerperium and post-natal care of the mother including a pelvic examination at the 6th week after confinement. The inclusive fee for this service is 7 guineas if the practitioner's name is on the obstetric list and 5 guineas if it is not. Where the complete service is not given the fees payable are as follows:

Services	Fee for Doctor on Obstetric List	Fee for Doctor not on Obstetric List
Period I Where the doctor gives the initial antenatal examination and subsequent supervision to the end of pregnancy including an antenatal examination at the end of the 36th week.	3½ gns	2½ gns
Period II Where the doctor is responsible for attending at the confinement (where necessary) and for post natal supervision including pelvic examination at 6 weeks after confinement.	4½ gns	£3 7s 6d
Other services (where payment for Period I or II not applicable) (a) antenatal examination only (b) post natal supervision only (including pelvic examination at 6th week)	10s 6d 1 gn	7s 6d 15s 0d

### Superannuation of Assistants

**Q**—I am a principal in general practice and on the list of an executive council. I employ an assistant whose name is not on the list of an executive council. As the assistant's name is not on the list, has the executive council any authority to require him to contribute to the superannuation scheme?

**A**—The Superannuation Regulations apply to an assistant practitioner whether or not his name is on the list of an executive council, provided his principal's name is on the list and

provided the assistant is wholly or mainly engaged in assisting his principal in the treatment of National Health Service patients.

### Partnerships and Superannuation Payments

**Q**—In *Questions Answered* (Nov 13 p 174) under the heading of *Partnerships and Superannuation Payments* it is stated that where the particulars of the partnerships are disclosed the deductions can be made according to the shares of the partners in the practice. Is the consent of both (or all) partners required for this? Any one partner who desired this arrangement could disclose the respective shares.

**A**—The appropriate regulation states

If the practitioner is a party with any other practitioner or practitioners to a partnership agreement, and particulars of the agreement are disclosed to the executive council, his remuneration shall be deemed to be such proportion of the total remuneration of such practitioners as the proportion of his share in the partnership profits bears to the total proportion of the shares of such practitioners in those profits.

It appears from this that particulars of the partnership agreement could be disclosed to the executive council by one partner with or without the consent of his other partner(s). The Insurance Acts (G M S) Committee is making representations to the Minister with a view to securing any alteration which may be necessary in the regulations to make it clear that there must be agreement between the partners before the executive council can be authorized to assess the superannuation contributions on the basis of the partnership shares.

## HEARD AT HEADQUARTERS

### Moscow Calling

Moscow has discovered that all is not well with our Health Service, and the other day took the trouble to tell us so in plain English. A broadcast asserted that the Health Bill came to nothing because "the Right Labourites surrendered to the capitalist Medical Association without even a fight" (*Listener* Nov 18). The Labour Government was blamed for not having nationalized the pharmaceutical industry, quackery still exists and doctors have become "merchants" in association with the commercial chemists resulting in the neglect of the sufferings of the people. We hasten to print this analysis of events lest Moscow accuse us again of misrepresentation. Eighteen months ago the *Meditsinsky Rabotnik* (Medical Worker) reminded us that "from time to time one finds in the *Journal* lines of which it is difficult to decide which is the greatest in them—malicious slander or limitless ignorance."

### B M A Film Library

The Association has started to build up a library of medical films, and it will soon be possible to borrow them. An excellent film on angina pectoris has been obtained which will be shown at B M A House in the New Year and will then be available for Divisional meetings. It is a full length film in colour with a spoken commentary and runs for about 80 minutes. Another film, "The Medical Motion Picture" which was presented by the American Medical Association depicts the advance of the film in the teaching of medicine from the early days of cinematography. This is also in colour and has a sound track.

### Free Treatment at Hospital

There is very widespread feeling that private patients ought to be allowed to obtain drugs and appliances free of charge under the National Health Service, and the B M A has repeatedly taken up the matter with the Ministry. The Minister has declared, however, that prescribing is inseparable from treatment, and that if general practitioner treatment is obtained by a private patient he must also pay for what is prescribed. A general practitioner tells us that he wrote to the Ministry asking whether his private patients could attend hospital and receive free treatment there under the Service. The Ministry agreed that they could. They would be entitled to free provision of any necessary drugs or appliances prescribed by the specialist responsible for their treatment.

## Correspondence

### Immediate Demands

SIR,—Reading the correspondence in the *BMJ* for the last few months it is clear that general practitioners are worried mainly by too much work and too little pay. While I agree with the opinions expressed in letters from Drs R J K Fleming (Sept 11, p 119) and D W Mayman (Oct 16, p 143) that a salaried service would be best for all parties, would facilitate work at health centres, and would avoid "head hunting," yet a salaried service alone cannot overcome our difficulties, and moreover is a solution as yet unacceptable to the bulk of practitioners and contrary to the promised amending Act. Others have suggested limiting the number of patients on a doctor's list to 2,000 or 2,500, and a capitation fee on a sliding scale two to three times the present size.

I feel it is time to decide on a definite policy capable of solving our problems within the framework of the Act. Having decided on such a policy it should be pursued relentlessly and vigorously until it has been achieved. For a campaign of this nature I suggest that we must avoid polemics on principles, which can only delay by tedious and fruitless discussion the practical changes we want. Equally we must avoid attempting to include every desirable change (and there are many changes which must be made in such matters as widows' pensions and the supply of drugs and dressings for surgeries, etc.) in a campaign policy. We should select the major essential points to make the GP service a success, and to rescue it from its present precarious condition. In my opinion our immediate demands should be as follows:

(1) The training of new doctors should be such as to increase the number of GPs to, and maintain it at, 1 per 1,500 of the population. This should mean that no doctor need have more than 2,000 patients on his list, and should allow for locums during holidays, sickness, postgraduate study, etc.

(2) The maximum number on any doctor's list should be reduced progressively as the number of doctors permits to 2,000 (or 2,000 per doctor where there are partners and/or assistants).

(3) The capitation fee should be based on the Spens Report, taking into consideration the year when the figures deduced were a true reflection of doctor's incomes. Proportionate increases should be made for all subsequent increases in the cost of living and for decreases in the maximum number of patients permitted on the list.

(4) The basic salary should be really voluntary, and should not be drawn from a pool in such a way that it decreases other practitioners' capitation fees.

(5) The building of health centres should be implemented without delay. They have a very important part to play in easing the doctor's work, increasing his efficiency, and making his work more interesting by increasing its scope. From the doctor's point of view health centres should provide: (a) secretarial staff, who would keep records in order, make appointments, deal with telephone messages, type letters, etc.; (b) nursing staff, who could deal with minor injuries and give various forms of treatment under the doctor's general supervision and assist in his clinical work at surgeries; (c) adequate facilities and apparatus for minor operations and other treatment or investigations not requiring specialist skill but difficult for single-handed practitioners in their own surgeries; (d) assistance, by relaying telephone calls and/or in other ways in the organization of off-duty times for the doctors as mutually agreed between them.

—I am, etc.,

Brighton

R S SAXTON

### The Bad New Days

SIR,—Bewildered at first when the first cheque arrived and believing there must be some mistake, and then angry and resentful as the realization grew on me of the enormous injustice that has been perpetrated on the profession as a whole, I have now reached the stage of near rebelliousness. Overworked we all are now, doing our bit to implement our side of the bargain. Having leaden hearts as we visit our patients trying to cheer them up, we ourselves are laden with a sense of injury and frustration, wondering how we are going to pay the rent, the bills, the children's education, the loans, and the overdrafts. We entered the Service with an idea of our duties, an outline of our remuneration, and "an eve of battle" address which said, Co operate and we shall enter into an era of prosperity and good health for doctor and patient alike.

We have done our duty, and what has been our portion? Interim payments which leave us little better off than manual labourers, if not worse in some cases, an announcement of further interim payments on the same scale, and nothing else. We have kept our side of the bargain. What about the other side? Not even the most gloomy prophets imagined a state of affairs as exists at present. We had misgivings, but we felt that if we worked in co-operation life would not be so bad—that if we did our bit to the best of our ability we could expect the Minister to do his, and that our profession would still be an honourable one and respected. Can any one of us look back on the "bad" old days and remember going on our bended knees to a patient and begging that our fees be paid? Can we feel honourable and respected when we have to crawl to the Minister and plead with him to honour his spoken pledges?—when we have to lay bare our poverty to the executive council and plead with it to consider us for the basic £300.

The patient is getting a square deal most definitely, but when is the Minister going to be told that it is not the Government that is at present providing this square deal? When is he going to be told that the doctor is working twice as hard for about two thirds of the pay he used to get, and that he is keeping the Service going out of his own capital and in many cases by means of loans and overdrafts on which he has to pay interest?—all this because the Minister delays in fulfilling his promises and furthermore withholds from us payments due. Is he going to pay us interest on the sums that he withholds? Is he going to pay the interest on the overdrafts and loans some doctors have been forced to raise to tide them over? It boils down to the fact that at present the doctors, chemists, dentists, and opticians are subsidizing the National Health Service out of their own private resources. The National Health Service is rapidly becoming for the doctors a horrible nightmare, penal servitude literally and metaphorically. What joy is there in work when one is worried to death at home? Where is the pleasure to be got out of employment when one has the feeling that the employer is ready to repudiate his commitments at the slightest provocation and go back on his spoken word? A farcical state of affairs exists. Assistants are actually receiving twice the remuneration of employers. Employers are receiving one half or two thirds of what was formerly considered fair pay, and all of us are working overtime.

The British Medical Association is very depressed. It admits that "it is up to the Government to meet promptly the causes of discontent which now prevail" (*Journal* Nov 13, p 864). We are fobbed off with similar statements—"The British Medical Association is bringing the matter to the notice of etc etc." "The Whitley Council is discussing

Negotiations are proceeding" and never do we hear of anything being fixed. All soporifics, but not strong enough to overcome the insomnia due to the worry and anxiety most of us feel. Why can't we have a definite lead from our central organization, or is it afraid to emulate the Medical Practitioners' Union with its screaming headlines for 30s capitation fee etc? We all know what is fair and just remuneration—viz Spens Report, 1939 plus 100% cost-of-living increase with none of these crazy deductions from a central pool infinitesimal mileage payments, and shoddy means tests for the basic £300. We need to present some such proposals to the Government and if they are turned down we can resign, emigrate or become dentists. The standard of work is bound to become lowered. If the Minister wishes a really good service he will have to pay for it. We cannot continue the subsidy indefinitely—I am, etc.,

Buckie Banffshire

A W McHARRIE

### Threaten to Resign

SIR,—I wish to add my protests to the many others regarding the unsatisfactory remuneration under the NHS. Like many of your correspondents' my practice is in a small semi-rural town where a once healthy private practice has disappeared to be replaced by a very busy, badly paid NHS practice. This seaside town houses a very high proportion of elderly retired people who require more attention than is normal in an industrial area where the population is active, working and where absence from work means loss of money. In addition our elderly patients expect visits to their homes and are averse to braving the inclement winter weather to visit a surgery. Consequently our expenses in running a car are increasing rather than decreasing.

It is therefore not surprising that I can only view with mounting anger and disappointment the timidity with which the question of increased remuneration is being tackled by our representatives on the Insurance Acts Committee. I note in the *Supplement* of Nov 20

182) that the above committee are proposing to start negotiations with the Minister for a proportionate increase in the capitation fee to offset the actual number of practitioners in the NHS—viz 19 400 as against the Minister's estimated 17 900. What a puerile suggestion to propose! Cannot the members of this committee realize that the present situation is not just a question of a slight readjustment of remuneration but is one full of the utmost urgency and calls for bold decisive action? If such action is not taken a great many ex-Service doctors like myself who have purchased practices and homes at heavy financial outlay in these post-war years and whose commitments are heavy, will not survive a long wrangle with the authorities nor will an increase of a few shillings in the capitation fee be of any value in relieving their desperate position.

It is obvious that we are all grossly underpaid and that many of us are heavily overworked. The answer is simple—the implementation of the Spens Report and this means a capitation fee of no less than 35s with a curtailment of lists to 2 500 or at the most 3 000. Whether the capitation fee is arrived at by a sliding scale or not is immaterial; the important point is that an average figure of 35s must be paid by the Government and that in retrospect to July 5.

It is time too that we realized that in joining the NHS we have not weakened our position, on the contrary we have strengthened our practices. A 90% resignation from the NHI scheme was organized when the Government refused to raise the capitation fee to 15s 6d, and it can again be organized just as effectively as previously.

Let the Insurance Acts Committee make their demand at once and back the demand with the threat of the wholesale resignation of the profession from the scheme unless our demand is met in full. We need have no fear now of loss of compensation or victimization. We hold the whip and the Minister must dance at our pleasure. If we do not take this action at once and back it with the threat of resignation we cannot expect the Minister to have any respect for our business ability and we can expect at some future date to arrive at the financial level now occupied by the teaching and clerical professions.

I conclude by reminding the profession that our auxiliaries—the opticians, dentists, and pharmacists, are now reaping a golden harvest while we take a back seat and allow the Government to pay these auxiliary professions with funds to which we should have prior claim. What the medical profession requires is a "fiery cross" and some of the brass neck of the miners and dockers. Let us take drastic action now before it is too late—I am, etc.

LARGE AYRSHIRE

WILLIAM R. MACKIE

### Capitation Fee

SIR—Judging by the correspondence on the unsatisfactory capitation fee, many of us have not yet realized that the State is not under contract to pay any particular fee to the doctors. I have signed a paper agreeing to do certain work for the Minister of Health but I hold no document stating that the Minister of the other party will pay me any particular salary and/or capitation fee and I have not heard that the B.M.A. or any other body holds such a document on my behalf.

So far speaking for myself I have received (on account) for three months' work a capitation fee of 5s, which for a rural practitioner covers the supply and dispensing of ordinary drugs and dressings etc. and I am unofficially notified that I shall receive the same for this quarter. The fee or salary is based on an 'if'. If so much in the pool, so much the capitation fee is near as possible to 15s per annum suggested by the Spens Committee on which presumably the B.M.A. was represented. True though it be that the Spens Committee suggested fee was related to N.H.I., but N.H.I. was so close to NHS that it automatically set the NHS fee.

As a profession we have been taken for a ride. Now that a State service is a fully established going concern, what is the position and/or function of the B.M.A. secretariat and executive in the Service? Are they in the Service as our representatives? Are they in as a Government public relations organization? Are they outside the Service and still trying to represent us? Or are they outside the Service negotiating for and representing those not yet in? Our economic position inside the Service is anything but rosy, both as regards remuneration and compensation for our business in spite of the nonsense talked about men with 4 000 patients earning £800 a year. If there are any of those they will not be long with us.

It is perfectly obvious that some newly formed representative body or the old one will have to take the strongest line of

action to get us a just if not adequate remuneration for the work we are called upon to do. At the moment I am doing twice the amount of work—not including forms etc.—that I did before NHS and my income is the same, and naturally my running expenses have increased. As far as I can gather from my colleagues the same applies to them. Mr. Bevins' exhortation to the public not to make too much use of the Health Service is very significant in more ways than one, he realizes that we are overworked, but will he realize that we are underpaid?—I am, etc.

St Osyth Essex

R. E. CLARKE

### Specialists' Appointments

SIR,—Could you or your readers help my insomnia? I lie awake at night worrying over my finances. I qualified 10 years ago and have spent this period, including four years in the Forces in obtaining higher qualifications and considerable experience as a first assistant. But there are no senior appointments advertised in my specialty.

In my region one of the most senior administrators proclaims his belief that the work of the "GP specialist" is "every bit as good" as that of the full-time consultant, and he practises what he preaches for many GPs here blossom as surgeons, physicians, anaesthetists, etc., one after noon a week to add £200 a year to the practice funds. These posts are not advertised before they are filled. An R.S.O. is made a full-time assistant surgeon by his benevolent administrator (privately arranged), a consultant at one hospital has been appointed to another as well (nobody knows exactly how)—and all since July 5. A GP friend of mine who bought a share of a practice which also gave him the right to beds in his local hospital tells me that he is waiting to learn the scales of remuneration before he decides whether to be a consultant or GP. He decides, it appears although he has never had any training in his specialty. Am I foolish in looking at your advertisement pages? Is it better to get to know someone and be quietly appointed?

The other attitude which worries me is very prevalent. "Poor old Smith, he's a terrible anaesthetist, but he has been on at his local hospital for so many years that one can't appoint a younger man, however more experienced and skilful—it might hurt Smith's feelings. (You be quiet, you're only the patient!)" A young dental friend with no house appointment, just out of the Services having made over £100 in his first week's work in the Scheme, wonders why I tried to get further experience after qualifying—he didn't.

Once all would be well on July 5. Now I am assured all will be properly arranged by March 31. I seem to have heard that before—I am, etc.,

Birmingham

REGISTRAR

### Employment of Assistants

SIR—Few could have expected before July 5 last that the NHS would have played the role of fairy godmother to the extent of providing us with assistants free of charge and I have no recollection that this was one of the Minister's inducements as suggested in Mr. Donald M. O'Connor's letter (*Supplement* Nov 13 p 177).

Mr. O'Connor appears to lose the whole point of the Training of Assistants Scheme. Surely it was never intended to subsidize the practice which needed an assistant in this way. If there was one on the pay roll of a principal on July 5 he must have been sufficiently trained to disqualify him from participating in the scheme as a trainee at the present time. The necessary qualifications for participation appear reasonable to me. Without them the whole project would be open to graft of the worst kind. One can imagine a state of affairs where two doctors "worked" a list of a few hundred patients in their spare time if these regulations did not exist.

For my part I regard the proposed scheme as the only oasis in this vast desert. I will be very disappointed if I am not recognized as a "trainer" even on the present terms. If the grant and allowances barely cover the cost of the assistant how refreshing it will be to welcome a flow of young enthusiasts into one's rather humdrum existence in a country practice where contacts with fellow practitioners are few and far between. The mutual advantages far outweigh financial considerations provided the latter are adequate. The training

process should hardly lead to premature cerebral arteriosclerosis in any of us. What a help it will be to have someone to take a few of these endless surgeries, give one a night or two in bed with the telephone switched off, and an occasional week-end in the company of one's family, and all for nothing with perhaps a few pence pocket-money left over—I am, etc.,

Brenchley Kent

W B HOWELL

### Intolerable Conditions

SIR,—In the Birmingham area I am led to believe that we are being paid 3s 11d per patient per quarter. Six to seven hours per day (and sometimes more) are taken up with "treating" patients who attend surgery. The remainder of the "eight hour day" is available for visiting patients. Night duty, of course, is extra.

It is very clear that medical practitioners in general are appalled at the remuneration of the National Health scheme and the amount of work it has given to doctors already over-worked. Conditions in general practice under the National Health scheme are intolerable, and I suggest that instead of constant and long drawn out negotiations the profession agrees to cease serving on a certain date, under the existing terms pending an immediate increase in capitation fee—I am, etc.

Birmingham

G A POWELL-TUCK

### Charge Patients for Service

SIR,—With regard to the numerous letters regarding remuneration, may I suggest that a charge of 1s per service payable by the patient to the doctor irrespective of the service involved would solve many of our difficulties? As I see it this would produce these benefits: (1) Reduce considerably those calls on surgery time for minor and trivial complaints, (2) increase our remuneration to a more reasonable figure, (3) give some feeling of economic satisfaction at the end of the day, a busy day tending to be regarded as a good day instead of a bad one as at present, (4) reduce the cost of the Service to the Government.

I have no doubt but that this would be opposed for political reasons, but I feel sure that the majority of us would agree that some such idea shows the common-sense way to overcome our two main troubles—overwork and underpayment—I am, etc.,

Leeds

S A SMITH

### No Hearing-aids

SIR,—It is really heartbreaking that in spite of what the Minister of Health has stated in the House of Commons all my patients who are in need of deaf-aids are, in response to their applications, receiving letters such as the following:

"In view of the fact that the Hearing Aid Clinic has not yet opened due to the complete absence of hearing aids, and as we now have the requisite number of patients to enable the Clinic to keep going for the first two months of its existence, we are not now making any further appointments for specialist examinations."

Having promised so much, so little has in fact been accomplished, with the result that those who need appliances are condemned to suffer not only disappointment but the knowledge that they must continue to do without until such time as the Government can fulfil its promises—I am, etc.

Sidmouth Devon

C J ST CUN

### Remuneration of G.P.s

SIR,—In the bulletin of the Oxford University Institute of Statistics for July–August, 1948, Mr Seers calculates the middle-class cost of living index for May, 1948, as 190% of the 1938 average. The calculation is based on the Ministry of Labour's new interim index of retail prices. The 1938 figures are substantially the value of money on which the Spens Report was based.

On this cost-of-living index the Spens Report figure for 50% of G.P.s in the age group 40–50 years becomes £2,470 net, and this at 35% of gross income for expenses gives a gross income of £3,800 per annum. The corresponding figures which 25% of the same age group should get are £3,040 net and £4,675 gross. The Spens Report also said there should

be no maximum sum. In listing the sources from which a G.P. might get income under the Service your annotation (July 17, p. 143) included interest on the sum to be paid for goodwill. I do not think this should be so included—I am, etc.

DAVID A PRIMROSE

\* \* The annotation states: "In addition the practitioner will receive yearly 2½% interest on the capital value of his practice as estimated for the purpose of compensation." This interest is not reckoned as part of the doctor's remuneration for work in the Service—ED BMJ

### A Sample Budget

SIR,—With so many theories being voiced as to the financial needs of a general practitioner I thought my own budget might be of interest. I am married with two children, a third expected in the spring, and with the hope of eventually four. My estimates for next year based on prices obtaining at present are as follows:

Housekeeping (food, etc.), £250 domestic help (with insurance) £130, mortgage, £235, clothes, £100, insurances, £150, car (at 6d a mile to include depreciation), £300, holiday, £75, secretary or receptionist, £100, telephone, £35, rent and rates (house), £140, rent of surgery, £50, heating and lighting, £50, superannuation, £90, income tax (approximately), £400, incidentals, £100. Total, £2,205.

The incidentals include charity, gifts to family and relatives and the many repairs and replacements needed in house and practice. Last year the actual amount was £268 but it was perhaps exceptional. It will be noted that there is no provision for capital saving, by that I mean trying to build up a bank balance now for a personal allowance to my wife. Being a non-drinker and non-smoker there is of course no provision in the budget. But what of the education of my children? There are no schools locally and I am faced with council schools or a bill of something between £400 and £500 a year for boarding-school fees.

It really comes down to this, that if the general practitioner is to be able to live a decent life and educate his children as he would like to, a minimum of £3,000 a year gross is necessary, for it must be remembered that the £400 income tax in the budget will be nearer £700 if this gross income is achieved.

My figures are based on actual experience. I will be only too happy to furnish any committee or board of inquiry with receipts for the past two years if any proof is considered necessary—I am, etc.,

P D

### Subsistence Allowance for Applicants

SIR,—Generosity in paying out-of-pocket expenses is to have no place, it seems, in the treatment of applicants for posts under the regional hospital boards. I have been asked to attend for interview for a post some considerable distance away, and it has been made clear to me that although I shall have to stay overnight (probably two nights) no subsistence allowance is payable according to a Ministry of Health ruling. Surely this is an unnecessary and niggardly departure from custom. I would point out that subsistence allowance is payable in the Services. It would appear that this is an example of economy strained to injustice—I am, etc.,

Oxford

G GORDON LENNON

### Compensation

SIR,—With reference to Dr A R Thatcher's letter under the heading "Independence of Government" Dr Thatcher states, "Not one of us has had a pennyworth of compensation yet nor knows what he will get." I think this statement sweeping, and perhaps to some degree damaging. I sent a letter claiming compensation on Oct 9 and on Nov 18 I had a Payable Order which was "an advance on account of the compensation to which you are entitled" (the quotation is from the Ministry of Health, Whitehall, SW 1).

I trust publication will be given to this letter. We cannot quite outlaw the question of "fair play" which still remains one of the "freedoms" we Englishmen enjoy—I am, etc.

Southampton

R FRANKING

## POINTS FROM LETTERS

## Capitation Fee

Dr E B ALLAN (Englefield Green Surrey) writes I write to urge for support of Dr S T Pybus's letter on capitation fee (*Supplement* Oct 16, p 143). The Insurance Acts Committee will be meeting shortly and with their help something could be accomplished. If the rural practitioner is not to be forced out of practice he must have the unanimous support of all his NHS colleagues and others for a resolution demanding the immediate increase of the capitation fee (along the lines suggested by Dr Pybus and others) to be made retrospective to July 5 1948, coupled with the implied threat of mass resignation to take effect on April 1, 1949, if the Minister has not seen fit to meet his just demands. The matter is urgent, and we must of necessity act immediately if the statutory notice is to be given to the local executive councils by Jan 1, 1949. There is much work to be done to organize the mass action which alone will bring about the desired result. The practitioners of rural and sparsely populated areas are left no choice but to take some such action unanimously or face financial suicide by accumulating bank overdrafts to subsidize the rural NHS. These practitioners can count to a very large extent on the support of their urban colleagues, because without it mass migration to the more populated areas would result, and consequently with their lists also reduced the urban doctors would then be in the same pitiable plight as their rural colleagues. The latter now find themselves with doubled duties with income cut to one half or one third—and in some cases without sufficient income to meet running expenses.

## Size of Lists

"DARE QUAM ACCIPERE" writes I would like to protest against the ideas put forward by many of your correspondents about the restriction of a doctor's list in the NHS. My partner and I with an assistant had 10,800 acceptances at the last check. We practise in an industrial area in a university town with a large and well known medical school. Within a radius of half a mile there are at least eight other principals not counting assistants. I specialize in one subject and have official appointments in it, our assistant has his L Med (Rotunda), my partner has been described to me by one of the honorary staff of the main hospital as one of the best types of family physician he knows. The reason we have a big practice is because we do not refuse calls. We examine our patients when there is an indication to do so and we take an interest in their families—sometimes our surgeries last 4-5 hours. It seems to me a very bad step to take to discourage keen men and encourage the man whose attitude is that he will only do as much work as will earn him what he considers a suitable income. The country can never be really served by such a policy. Who can judge better than his patients what service a doctor gives? If people prefer to wait 2-3 hours to see a particular doctor, whereas they could see someone else in half an hour, they must have a good reason. No, Sir, to my way of thinking let each man do what he can. I do think the country practitioner needs special terms, because of course no matter how keen and good he is he cannot make a living out of 2,500 or so patients and his idleness is not due to choice. The answer is a very generous mileage and drug allowance to subsidize him. The sluggish thinker will have time to do his work.

## The Doctor's Wife

A Doctor's Wife writes This is a widespread country district and the number of patients on our list compares unfavourably with a town practice. On the facts so far known to us about the new Service we can expect to be reduced to about half our previous income. The work has rather increased than diminished and no cut in our heavy expenses seems possible, especially where car and telephone are concerned. I have no resident help in the house, and any assistance I require to keep house or garden in order I have to employ by the hour—a very expensive way, but the only one available to me. This means of course, that I have to work very hard. If at any time I wish to leave the house I have to make elaborate arrangements on the same hour basis for somebody to take my place in case of telephone messages. In the past I have at least felt that intermittently I could afford to do so but in view of our balance sheet under the new scheme we are forced to cut down all expenses in every possible way to keep our heads above water. We still owe money on the original purchase of our practice, but we are informed by our accountant that we are not considered a hardship case. It does seem however unfair in the extreme that we should continue to pay interest of 4½% while the Government is only prepared to refund us 2½% on our debt. The sum total of my new experience under State medicine is that, while my unpaid service in it is taken for granted my task is made much harder through constant financial worries and the diminishing prospect of adequate remuneration for my non-stop duties. I am in fact working under conditions which would be quite unacceptable to any employee or union member.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Willsend

*Urban District Councils*—Denton, Droylsden, Houghton le Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley

## Association Notices

## OPHTHALMIC GROUP COMMITTEE

The following have been elected to the Ophthalmic Group Committee as representatives of non members of the Ophthalmic Group who are on the General List of Practitioners entitled to participate in the Supplementary Ophthalmic Service: R G Simpson, C M Stevenson

## Diary of Central Meetings

## DECEMBER

9 Thurs Journal Committee 2 p.m.

## Branch and Division Meetings to be Held

**CITY DIVISION**—At St Leonard's Hospital, Nuttall Street, London N, Tuesday, Dec 7, 8.30 p.m. Clinical lecture by Dr Leonard Simpson 'Thyrotoxicosis and its Treatment'

**EAST HERTS DIVISION**—At Lister Hospital, Hitchin, Thursday Dec 9, 9 p.m. Joint meeting with South Bedfordshire Division. Clinical cases will be shown.

**GUILDFORD DIVISION**—At Royal Surrey County Hospital, Guildford, Wednesday, Dec 8, 8.30 p.m. Dr W P H Sheldon 'Stomatorrhoea in Childhood'

**HENDON DIVISION**—At Hendon Hall Hotel, Wednesday, Dec 8 Dr J Purdon Martin 'Penicillin and Streptomycin in Neurology'

**MONMOUTHSHIRE DIVISION**—At St Mellons County Club, St Mellons, near Cardiff, Monday Dec 6, 8 p.m. Annual Dinner Dance

**NUNEATON AND TAMWORTH DIVISION**—At Red Lion Hotel, Atherton, Tuesday, Dec 7, 8.30 p.m. B.M.A. Lecture by Mr Harold Dodd 'The Vancosites'

**PORTSMOUTH DIVISION**—At Kimbells Corner House, Commercial Road, Portsmouth, Tuesday, Dec 7, 8.30 p.m. Dinner Meeting Address by Dr C Keith Simpson 'Some Difficulties in Scientific Crime Detection'. To be illustrated by lantern slides and followed by a discussion.

**SOUTH ESSEX DIVISION**—At Old Church Hospital, Romford, Friday, Dec 10, 9 p.m. Clinical meeting. Interesting cases will be shown.

**SOUTH WALES AND MONMOUTHSHIRE BRANCH**—At Royal Gwent Hospital, Newport, Monmouthshire, Thursday, Dec 9, 3.30 p.m. Clinical meeting.

**TUNBRIDGE WELLS DIVISION**—At Kent and Sussex Hospital, Wednesday, Dec 8, 8.15 p.m. Dr C J C Britton 'Diagnosis and Treatment of Anaemia'

## Meetings of Branches and Divisions

## BIRKENHEAD AND WIRRAL DIVISION

At a well attended meeting of the Division on Nov 7 a paper on 'The Proposed Formation of a Medical Trade Union' was read by the chairman Dr H S Pemberton. This was followed by a long discussion. It was felt that the kindly negotiating machinery of the British Medical Association was no longer sufficiently adequate to put forward and attain the just claims of the medical profession. The following resolution was passed unanimously: 'That this Division recommends the formation of a trade union within the framework of the British Medical Association, this being in our opinion the best way of safeguarding our interests'. The secretary was instructed to circulate a copy of the memorandum and resolution to all Branches and Divisions and also to B.M.A. Headquarters.

## GENERAL MEDICAL COUNCIL

Owing to the restrictions on our space we have had to hold over until next week our report of the 174th session of the General Medical Council.

## PROPHYLAXIS OF VIRUS INFECTIONS, WITH SPECIAL REFERENCE TO THE USE OF VACCINES\*

BY

C H ANDREWES, MD, FRCP, FRS

National Institute for Medical Research London NW 3

When discussing the prevention of virus diseases we should consider both non-specific hygienic measures and specific prophylactic vaccination. I will not deal with the hygienic aspects, which for some viruses may be more important than inoculation. It may, however, be noted in passing that with regard to some of the more important viruses we are still ignorant of the relative importance of various modes of transmission and therefore do not know upon what hygienic measures to rely. There is still dispute about how the poliomyelitis virus most commonly spreads—by manual or fly-borne contamination or by inhalation. Even in the case of the big group of air-borne upper respiratory infections we know less than we thought we knew some years ago. Are the minute droplet nuclei most important? Or the coarser particles which fall quickly and dry up, and which are then re-dispersed as dust? Or the infected particles spread by the shaking of handkerchiefs and the shaking of hands? I must leave this matter now, except to plead for more fundamental work on modes of transmission as a necessary first step to putting effective hygiene into operation.

### Immunity in Virus Diseases

In 1931 I gave a lecture on immunity in virus diseases (Andrewes, 1931). The matter has been discussed many times before and since then, but there seem to be no new principles to bring to your notice. With the old principles you are doubtless familiar enough. Many viruses are conveniently adaptable, patient search and chance have placed in our hands modified viruses attenuated enough to be capable of being used with safety in the living state yet sufficiently unchanged antigenically to give potent and sometimes enduring immunity. Yellow-fever vaccine, which is in this class, sets us a standard to which we would like all vaccines to attain—a single dose which causes no inconvenience, or at most a slight headache, and an immunity so long that we may almost say, "It may be for years, it may be for ever." The modified yellow-fever virus, 17D, now used for making such vaccines, turned up somewhat fortuitously, deliberate attempts to produce another, equally useful, variant virus failed. Lately, so many viruses have been grown and attenuated by growth in fertile eggs that we may hope for more conveniently modified variants to be discovered.

Some viruses can be inactivated, apparently irreversibly, by formaldehyde or other means and still immunize. Large doses must be given in order that enough antigen may be introduced, and these large doses may cause local reactions. A limit may thus be imposed on what can be conveniently

given. Immunity after the giving of killed vaccines is much less durable than after the best of the live attenuated vaccines, raised immunity for a year is the sort of result to expect. Formaldehyde is the most generally used inactivating agent, but others, particularly ultra-violet irradiation, are proving to have advantages in some instances. For reasons obscure to us, inactivated vaccines immunize fairly well against some virus diseases—for example, influenza—and very poorly against others—for example smallpox.

I now turn to discuss two general aspects of virus-prophylaxis: the importance of serological strains of viruses, and the possible application in practice of the so called interference phenomenon. Influenza affords the best illustration in both instances.

### Serological Races of Viruses

We are increasingly forced to realize that many viruses, like many bacteria, have serological races differing enough to affect the results of attempted vaccination. This is true of influenza and poliomyelitis among human diseases. The variations among the influenza and poliomyelitis viruses are far from being understood. Fortunately, variola, yellow-fever, measles, mumps, and some other virus infections are, so far as we know, not apt to vary in antigenic make-up in such a troublesome way. There are two distinct influenza viruses, A and B, believed to be antigenically unrelated to each other. A seems to be the more important. It is within these two groups that minor variations occur to vex us. There are certain classical strains of influenza A studied in laboratories all over the world—the original WS, the PR8, and the Melbourne strains. Whenever in a fresh outbreak new A strains are isolated they are found to differ in serological and cross-immunity tests from these classical strains, and usually, so far as has been tested, from strains recovered from other epidemics. There are always significant cross-reactions, and any two strains may be fairly close together or rather wide apart. Unfortunately there has been no detailed comparison of strains collected from outbreaks in different years in any one country or from different countries in the same year. Therefore we do not know whether there exist limited numbers of types, as with pneumococci and other bacteria, or whether the influenza A virus is capable of an indefinite number of biochemical modifications of a basic structure.

The antigenic variations are important from the points of view of vaccine preparation and of epidemiology. Vaccines have been made in the United States from fluids of infected hens' eggs. In the autumn of 1943 against an A epidemic, and in 1945 against a B outbreak, these vaccines gave most encouraging results. In 1943 the vaccine—in five out of six centres at any rate—apparently reduced the

\*Read in opening a discussion in the Section of Pathology and Bacteriology at the Annual Meeting of the British Medical Association, Cambridge, 1948.

incidence of A infection fourfold (Commission on Influenza 1944). In 1945 a tenfold to twentyfold reduction of B influenza seemed to have been achieved (Francis *et al* 1946, Hirst *et al* 1947). The 1943 trial was favoured by two factors: first the epidemic hit the communities under observation only a week or two after the vaccinations and secondly there had been incorporated in the vaccine a very recently isolated strain obtained from a local outbreak in the previous spring. There was a rather rapid assumption that the problem was solved: over 5 million doses of vaccine were given to American troops in 1943-4, and still more in 1945-6. Doubtless the influenza virus chuckled to itself, and quietly mutated to a sufficiently distinct form. At any rate numerous American trials of vaccine in 1947 showed a total absence of protection against the 1947 brand of influenza (Francis *et al* 1947). Tests in this country were almost equally discouraging (Mellanby *et al*, 1948). I have been told that vaccines now being made in the U.S.A. contain recently isolated strains, but I fear that the virus is still chuckling, and that until we know more about its possible range of variation it is useless to produce vaccine on a vast scale. Trials of aspects of vaccine making and testing, other than those concerned with antigenic variants, are of course needed all the time.

Influenza A in America and over here has a 2-3-year periodicity. Influenza B, which is probably a more effective antigen, has a longer, 4-6-year cycle (Commission on Acute Respiratory Diseases, 1946). The fact that the cycles have any regularity at all probably depends on a regular rate of waning of herd-immunity. The periodicity is unfortunately not so regular that we can prophesy with confidence that any particular year will or will not have an influenza epidemic. This lack of precision is perhaps due to this same faculty of the influenza viruses for antigenic variation. If a mutant happens to turn up unusually remote from previous strains it will be able to spread widely and initiate epidemics earlier than would otherwise be the case. In 1945-6 there was good evidence that influenza B was unusually active all over the world, beginning in the mid-Pacific, spreading south to Australia, east to the Caribbean, to North and South America, and later to Europe (*Bull. U.S. Army med. Dept.* 1945). In 1947 at least one of the novel antigenic types of A which successfully defied the vaccine in America proved to be identical with strains current over here at the same time. All this suggests that the epidemiology of influenza needs to be studied on a world-wide basis.

The World Health Organization has accordingly obtained the consent of the Medical Research Council to set up at the National Institute for Medical Research at Hampstead a World Influenza Centre. This will gather information about the doings of influenza all over the world, and will collect from and distribute to interested laboratories strains of virus. It is hoped that regional influenza laboratories in other countries will collaborate, particularly in collecting local strains, and that we may in time obtain some picture of the behaviour of influenza on a canvas which is really world wide. If it should appear that new strains are in fact globe-trotters, the possibility exists of anticipating their arrival from abroad and greeting them with really homologous and therefore effective vaccines.

The occurrence of poliomyelitis outbreaks seems related in part to the hygienic conditions of a country and to the opportunities for exposure to virus during infancy. But on top of this is the likelihood that serological variants of poliomyelitis may be spread about distinct enough to be able to infect people with good resistance to a local strain. The epidemiology of both influenza and poliomyelitis is complex: common to both is a major cause of the complexity is the problem of antigenic variation. We have

not yet got a vaccine of real promise against poliomyelitis, even if we had one, we should still have to sort out the antigenic variants of the virus.

### 'Interference' as a Prophylactic Measure

Against a rapidly spreading influenza pandemic of a new type the most rapid vaccine production might well be much too slow. On this account Burnet and Foley (1940) have urged that we should seek attenuated viruses which can be given in the living state by the respiratory route: these could be given in relatively much smaller dose and thus be prepared for large populations much more rapidly. Unfortunately trials with such attenuated influenza viruses in man have not yet given encouraging results. An approach similar to this involves the attempted practical application of the so-called "interference phenomenon". Virus-workers have known for over a decade that certain viruses will interfere with or suppress the activity of other viruses inoculated at the same time or shortly before. The two viruses may be variants of one species, as in the interference of neurotropic with viscerotropic yellow fever (Hoskins, 1935), or two antigenically related species or even two antigenically unrelated species. Possibly similar effects are dependent on different mechanisms in different instances.

The phenomenon can most easily be studied as it concerns the exclusion of a phage particle from attack upon a bacterium by another phage which has got there first. Apparently even one phage particle can so modify the bacterium, perhaps its surface, perhaps its enzyme equipment, that particles arriving later are unable to enter and have to stay outside and starve (Delbruck, 1945). The phage arriving first can still exclude the one arriving second though the former has been inactivated by ultra-violet irradiation. The phenomenon as regards animal pathogenic viruses is most easily studied in those which grow in the fluids of infected fertile eggs. Is it, one wonders, something of purely academic interest, invented to amuse virus workers in their laboratories, or does it play a part in epidemiology in real life and can it be applied to the control of disease?

Interference by one influenza virus with another can be shown very readily in infected eggs, but in my experience is much less easily demonstrated in infected mice. Lately my colleague, A. W. Gledhill, and I have been carrying out experiments in ferrets with more success. We used a strain of influenza B which caused practically no fever or symptoms in ferrets. This was given to ferrets intranasally and followed one, two, or three days later with a dose of virus A which produced severe symptoms in control animals. In the B-treated ferrets no fever or symptoms developed either from the B or subsequent A infection, and the ferrets were later immune to both viruses. The B by itself induced no true immunity to A, for if the interval between giving the B and the A viruses was extended to a week or more the A infection pursued its normal course or was even worse than usual. The interference is thus effective for a very limited period, presumably while an actual though inapparent, B infection is in progress. As yet we have been unsuccessful in interfering with an A infection by means of an attenuated A strain. Our results are brought a step nearer to practical application by the finding that B infection also protected ferrets against A when they were exposed for two days to contact with other A-infected ferrets. Controls were readily infected by such contact. These experiments can be repeated regularly but only within rather narrow experimental limits, and possible practical application depends on the results of much further work. It seems however, worth while to

draw attention to the possibility of preventing virus disease in the future by means rather different from orthodox immunological methods

### Recent Progress in Prophylaxis of Other Virus Infections

I will conclude with some very brief items of news concerning other viruses not already mentioned

**Mumps**—Mumps virus has now been grown in fertile eggs and has been shown to resemble influenza A and B, fowl-plague, and Newcastle disease of fowls in its ability to agglutinate red blood cells of certain species. These five viruses seem to form a natural group. Like influenza, mumps can be modified by egg passages, and there are hopes that an attenuated virus suitable for immunization of man may be developed (Enders *et al* 1946). Gamma-globulin prepared from mumps convalescent serum has been stated to be of value in preventing orchitis when given early in the disease (Gellis *et al* 1945).

**Measles**—Measles virus has also been cultivated in eggs, but its presence can be recognized only by transfer back to rhesus monkeys or human volunteers. Egg-passage attenuates it for children but one cannot yet advocate its practical use for immunization. Its attenuation is not quite enough to satisfy us, on the other hand the immunity produced is far from complete (Stokes *et al* 1943). Prevention or attenuation of measles by immune serum is an old story. It may be noted, however, that for this purpose concentrated gamma-globulin is better than placental globulin (Greenberg *et al* 1945).

**Rubella**—This has not yet been transmitted to laboratory animals, and the gaining of knowledge about it lags accordingly. Literature is piling up (Editorial, 1947) concerning the occurrence of congenital abnormalities such as cataract in babies born of mothers who suffered from rubella in the early months of pregnancy. Common sense will warn us to shield such mothers at all costs from unnecessary risk of exposure to the disease.

**Rabies**—It has been claimed that animals may be experimentally protected against rabies more effectively by concentrated immune rabbit serum than by traditional vaccines (Habel, 1945). Many people wonder whether if Pasteurian vaccines do prevent rabies the effect is not due to something like the interference phenomenon I discussed earlier rather than to immunization in the usual sense. I say advisedly if they are effective, for I note with surprise how little notice is officially taken of the late L. T. Webster's (1942) challenge in his book on rabies. He maintained that there was very slender scientific evidence that such vaccines prevented rabies at all when given after infection.

**Smallpox**—Experience in the recent war confirms our belief that because of varying susceptibility and immunizability, vaccination cannot be depended upon to protect an individual *but* (and may no one quote the first half of this sentence away from its context) vaccination is still a reliable means of preventing and controlling smallpox outbreaks since it will protect most subjects. It has been known for some years that vaccinia grown in tissue cultures or in fertile eggs can be obtained free from all bacteria, and that such a vaccine will immunize man (Buddingh 1943) but this method of vaccine manufacture has not yet been taken up and seriously tested in comparison with calf or sheep lymph.

**Encephalitis**—Viruses cause several forms of mosquito-borne encephalitis in America and the Far East. There is, also in Russia a tick-borne encephalitis related to the louping-ill of sheep which occurs on the Scottish borders. Against all of these infections formalinized vaccines seem to confer a considerable degree of protection. The cause of sporadic encephalitis in this country is unknown.

**The Common Cold**—Work on the aetiological agent at the common cold research unit at Salisbury continues. We have not yet succeeded as two groups of American workers claim to have done, in growing a virus in eggs. Nor I need hardly say, have we yet produced a vaccine.

More virus vaccines in the future are likely to be made in fertile eggs. At present yellow-fever vaccine, so grown is of proved value so is influenza vaccine within the limits I have discussed. Nearly all the development in this field is going on overseas. I believe that far-sighted manufac-

turers of biological products in this country would do well to gain experience in this field and contribute their share to its development.

 London Formerly Assistant to the Pathologist Brompton  
 Hospital

Strains of *Mycobacterium tuberculosis* isolated from patients before treatment are remarkably uniform in their sensitivity to streptomycin (Middlebrook and Yegian 1946, Youmans and Feldman, 1946, Medical Research Council 1948c). However, during the course of treatment strains often develop a variable degree of resistance to the antibiotic (Youmans *et al*, 1946, Report to Council on Pharmacy and Chemistry, 1947, Canada, 1947, Hinshaw and Feldman, 1947, Fisher, 1948, Sadusk and Swift, 1948, Medical Research Council, 1948b). A controlled series of cases of pulmonary tuberculosis has been treated with streptomycin under the auspices of the Medical Research Council, and the result of these trials is reported elsewhere (Medical Research Council, 1948a). Among the group of patients receiving streptomycin, 13 were treated at the Brompton Hospital, and from these were obtained sufficiently detailed data on the development of streptomycin resistance to justify a further report.

### Method of Investigation

**Type of Case**—Patients were aged from 15 to 30 years and suffered from acute progressive bilateral pulmonary tuberculosis of recent origin. Cavitation was present in all. Before treatment 11 had numerous acid-fast bacilli in direct smears of the sputum, 2 had acid-fast bacilli present only in sputum concentrated or in small numbers in direct smears. There were 10 women and 3 men.

**Dosage of Streptomycin**—Every six hours 0.5 g. was given intramuscularly. In the earlier part of the trial treatment was continued for six months but this was later

\*In receipt of a grant from the Medical Research Council

modified to four months. As a result, of the 13 cases 8 had four months' treatment, 3 had between four and five months' treatment, and 2 had between five and six months' treatment.

The observation period was six months, except for one patient from whom a resistant strain of *M. tuberculosis* was isolated for the first time during the seventh month.

**Clinical Data**—Clinical examinations were made on each patient at monthly intervals and included an x-ray examination of the chest. Patients were weighed weekly, except some who were very ill, and the erythrocyte sedimentation rate (Westergren) was measured fortnightly.

**Assessment of Clinical Progress**—Each patient's progress was assessed by scoring based on the clinical data and on the temperature. As a measure of x-ray progress the independent verdicts of the Medical Research Council panel were taken. Marks were awarded as follows:

	Great Improvement	Improvement	No Change	Worse	Much Worse
Cough		+1	0	-1	
Quantity of sputum		+1	0	-1	
General condition	+2	+1	0	-1	-2
X-ray film	+4	+2	0	-2	-4

**Temperature**—This was based on the average of evening temperatures each month.

Fall from over 100° F (37.8° C) to under 99° F (37.2° C) +2

Over 1° F (0.55° C) fall +1

1-2° F (1.1° C) rise -1

More than 2° F rise -2

**ESR** (In all relevant cases the initial ESR was 40 mm/hour or over)

Reduced to under 50% +1

Increased by over 100% -1

**Weight changes in a two months period**

Gain of 10 lb (4.5 kg) or over +3

" " 7 to 9 lb (3.17 to 4.08 kg) +2

" " 3 to 6 lb (1.36 to 2.72 kg) +1

Loss of 3 to 6 lb -1

" " 7 to 9 lb -2

" " 10 lb or over -3

No doubt many will differ about the importance allotted to the various clinical observations, but the method does form a basis of comparison between cases, and it provides a clinical scale for correlation with the development of streptomycin resistance in the strains of *M. tuberculosis* isolated.

**Degree of Cavitation**—The estimate of the degree of cavitation shown on the initial x-ray films was made by Dr Peter Kerley for the Medical Research Council.

**Sputum Examinations**—These were made at short intervals, often twice a week and never less than once a month. During the period at which streptomycin-resistant strains first occurred many cultures failed to grow *M. tuberculosis* so that the intervals between positive cultures were longer than had been hoped for.

**Technique of Testing for Sensitivity to Streptomycin**—The sputum was treated with 4% sodium hydroxide, centrifuged and neutralized, and the deposit inoculated on to Lowenstein-Jensen slopes, which were incubated for nine weeks. The strains of *M. tuberculosis* isolated were subcultured into a synthetic medium containing Tween 80 (Honeywell and Stein, St James's Square, London) and albumen (Dubos and Davies, 1946), and an inoculum from this was put into bottles of the same medium containing streptomycin. The minimum level of streptomycin inhibiting growth after 10 days incubation was taken and compared with the level necessary to inhibit a standard strain (H37Rv), which was treated in the same manner. When, for instance, the concentration of streptomycin inhibiting the organism under test was 32 times that inhibiting the

standard strain the streptomycin resistance of the test organism was said to be 32 times that of H37Rv. This comparison is taken as the basis of the measurement of the degree of resistance. The technique is fully described elsewhere (Medical Research Council, 1948c).

**Degree of Resistance**—In order to obtain comparative figures in analysing our results we have taken the degree of resistance as the average (actually the geometric mean) of all the resistance tests carried out on each case after a plateau level, as described below, had been obtained.

**Date of Development of Resistance**—By 'date of development of streptomycin resistance' we mean the first day of streptomycin treatment on which a culture was obtained that proved to be four or more times less sensitive to streptomycin than H37Rv. To compare the different cases we have thought it best to take the mean between the last day on which a sensitive culture was obtained and the first day yielding a resistant culture. We have called this the "mean day of resistance development".

## Results

**Strains Isolated before Streptomycin Treatment**—From most cases two positive cultures were obtained before streptomycin treatment. These strains were either two times less sensitive than H37Rv, two times more sensitive, or equal in sensitivity, except one strain, which was four times less sensitive.

**Development of Streptomycin Resistance**—The times taken for resistance to develop and the degree of resistance attained are recorded in Table I, and examples are illustrated in Fig. 1. Certain comments can be made on these

TABLE I—Degree of Streptomycin Resistance and the Time at which it Developed

Case No.	Last Day when Sensitive Culture was Isolated	First Day when Resistant Culture was Isolated	Mean Day of Resistance Development	Degree of Streptomycin Resistance	Clinical Progress Before Development of Streptomycin Resistance	Clinical Progress After Development of Streptomycin Resistance
87	22	42	32	251.2	-1	+1
100	36	42	39	309.2	+3	+5
86	37	47	42	97.9	+3	+6

94	33	61	47	85.1	+7	+4
99	36	60	48	10 000 or more	+7	+7
83	47	49	48	77.6	+7	+6
79	56	76	66	31.6	+7	+7
95	56	77	66.5	40.7	+7	+7
82	65	74	69.5	3.4	+6	+6
89	28	189	108.5	64.0	+11	+6

The mean day of resistance development is the mean day between the last sensitive and the first resistant culture. The degree of streptomycin resistance is the average of all the tests done after resistance had risen to a plateau level; the figures are in multiples of the streptomycin resistance of the control strain (H37Rv) and were obtained by taking the antilogarithms of the average of the logarithms of the original figures. The method of assessing clinical progress is described in the text.

In all cases there was a period following the beginning of treatment during which the strains of *M. tuberculosis* remained sensitive to streptomycin. In 12 out of 13 treated cases there was later an indication of increased resistance to streptomycin. In 11 out of these 12 the strains were 32 or more times less sensitive. In the twelfth case (Case 82) the strains remained approximately four times less sensitive over a period of more than six months after beginning treatment. Subsequently 1 ml of an eight-day growth in Dubos-Davis medium of a strain isolated from this case before treatment was started was inoculated into a 25-ml quantity of the same medium containing 1,000 µg of streptomycin. From this flask a strain was obtained after six weeks' incubation which, when tested by the technique used in this investigation, was 2,000 times less

FIG 1—Examples of development of streptomycin resistance in cases under treatment. Note that Cases 82 and 95 are included as unusual examples. Cases 83 and 86 are more typical.

sensitive than H37Rv. This work was performed by Miss M E Davies at the Postgraduate Medical School of London. It is thus clear that this strain is potentially capable of producing highly resistant variants. The thirteenth case, in which resistance was not observed to develop, yielded a sensitive culture on the 59th day and subsequent cultures were negative. A further case (No 89) yielded a sensitive culture on the 28th day. Repeated cultures were then sterile till the 189th day, when two grew strains 64 times less sensitive than H37Rv. Since then all subsequent cultures have failed to yield *M. tuberculosis*.

In most cases the level of resistance rose fairly rapidly to a maximum value and then remained at about the same level. After resistance first appeared isolated sensitive strains were obtained in three cases within 15 days, but not after that time. One of these (Case 97) was of special interest. The first resistant culture was obtained on the 51st day of treatment, and was over 4,000 times less sensitive than H37Rv. The sputum was then negative for a fortnight, at the end of which it became blood-stained. This specimen of sputum was noticeably more purulent than previous specimens and contained numerous acid-fast bacilli. On two occasions cultures yielded strains which were sensitive. After this the sputum became negative by smear and culture, and has remained so for a further 14 months.

Streptomycin resistance was observed to develop in cultures from three patients whose sputa subsequently became negative (Cases 79, 89, and 97).

**Numbers of Tubercle Bacilli in the Sputum and Development of Resistance.**—Fig 2 shows that, if bacilli persisted in the sputum, in most cases the number diminished under treatment to a minimum occurring at or after the time that resistance developed. After this the number again increased.

**Additional Notes on the Development of Resistance.**—In one case (No 92) sensitive tubercle bacilli were cultured from urine after more than three months' treatment and after the strains from the sputum had been consistently highly resistant for six weeks. In Case 99, dying eight days after finishing treatment and whose sputum cultures had been at least 4,000 times less sensitive than H37Rv, 18 cultures were taken post mortem from different parts of the lungs and all showed the same high degree of resistance.

In two cases resistance tests were done on individual colonies from cultures which routine tests had shown to be resistant. In the first case (No 92) the culture was the first one shown to be resistant, and was obtained seven days after the last one known to be sensitive. By the routine test the culture was 128 times less sensitive than H37Rv. The growth was a heavy one, and from it nine colonies were selected and tested individually for sensitivity. Four were of the same sensitivity as H37Rv, two were four times less sensitive, two were 64 times less sensitive, and one was 128 times less sensitive. In the second case (No 94) the culture was the second one shown to be resistant. It was obtained 33 days after the first resistant culture and 61 days after the last sensitive one. Growth was moderate, and the culture was 64 times less sensitive than H37Rv by

FIG 2—Degree of positivity of sputum in relation to development of streptomycin resistance. Ordinates indicate degree of positivity, 0=negative to smear and culture, 1=culture only positive, 2=positive on concentration, 3=moderately positive on direct smear, 4=strongly positive on direct smear. The arrows indicate when the first resistant culture was obtained. The monthly positivity figures are based on three examinations in most cases. Other results are indicated only where they are important.

the routine test. Fifteen colonies were selected for individual testing. One was 16 times, 5 were 32 times, 8 were 64 times, and one was 128 times less sensitive than H37Rv. It is of interest that in this case, where the culture was obtained at least a month after resistance had developed

higher proportion of the colonies were resistant than in the first case, where the culture was the first one shown to be resistant

### Analysis of Results

An attempt was made to correlate the mean day of development of resistance, the degree of resistance attained, and the clinical progress both before and after the development of resistance. Using the system of scoring previously described, Spearman's rank correlation coefficient was calculated and a test of significance applied, making the appropriate adjustment for the small number of cases. Student's  $t = \rho \sqrt{\frac{n-2}{1-\rho^2}}$  (Kendall, 1943). The results are indicated in Table II. This coefficient was used rather than the usual

TABLE II—*Correlation of Streptomycin Resistance of Tubercle Bacilli with Certain Factors*

Not —Correlation coefficients in bold type are considered statistically significant since the probability of their occurrence by chance is less than the conventional 1 in 20.

correlation coefficient, since it seemed possible that the degrees of resistance developed were not arranged in a normal distribution. One of the determinations of the mean day of development of resistance was obtained only within very wide limits (Case 89). Two sets of figures are given, one excluding and the other including this result. There was an apparent relation between the mean day of resistance development and the clinical progress before development of resistance if the values include results from this case. If, however, these results are not included the correlation coefficient is only suggestively high. Cases which did poorly developed resistance early (Fig 3).

There was a definite relation between the clinical progress before resistance developed and the degree of resistance that eventually occurred (Fig 4). Those cases doing well in the early stages of treatment developed a low degree of resistance, while those doing poorly produced more highly resistant organisms. This correlation was significant. There was also a significant correlation between the mean day of resistance development and the degree of resistance eventually achieved. The higher the degree of resistance the more rapidly did it appear (Fig 5).

There was no significant correlation between the mean day of resistance development or the degree of resistance that developed and the clinical progress after that development, nor was there any demonstrable relation between the time at which resistance developed and the general con-

dition on admission as assessed either on general clinical grounds or as the average evening temperature before treatment was begun. A dot-diagram suggested a possible relation between the degree of resistance and the average evening temperature: those with higher average temperatures tended to develop higher degrees of resistance and vice versa. This relation was not, however, statistically significant. There was no significant relation between the

FIG 3—Relation of mean day of resistance development to clinical progress before resistance had occurred. The boxes indicate the main groups into which the cases fell.

mean day of resistance development and the extent of cavitation before treatment, though there was some suggestion that those with lesser degrees of cavitation developed resistance later, and vice versa. No relation could be shown between the degree of resistance and the extent of the cavitation. Our failure to demonstrate these relations is not, however, conclusive owing to the small number of cases.

**Clinical Effect of Resistance Development**—The clinical progress of our individual patients during their streptomycin course before and after the development of resistance, is shown in Fig 6. It will be seen that in only two cases did any great change in the clinical course coincide with the first demonstration of streptomycin resistance (Cases 83 and 86). In Case 82, in which there was an apparent change, resistance did not rise above four times that of H37Rv during the relevant period. Two cases which went downhill from the start (Nos 87 and 99) perhaps showed some slowing in the deterioration before resistance developed and thereafter deteriorated more rapidly, but one cannot say that this acceleration might not have occurred if no streptomycin had been given.

**Factors other than Streptomycin Resistance which may affect the Response to a Course of Streptomycin**—As we have not in most of our cases been able to demonstrate

a close relation between the development of resistance and the subsequent clinical course, we have considered what other factors might be involved. Two obvious factors are persistent cavitation and the patient's own defences. This latter factor is very difficult to assess, but we have attempted a rough estimate by comparing the patient's progress before streptomycin treatment with the extent of his disease as

shown radiologically. We have tried to assess for each patient the relative importance to the outcome of the streptomycin course of residual cavitation, the patient's own defences, and, where it occurred, streptomycin resistance. Such an estimate can, of course, be only very rough, but it may serve to suggest the different factors involved.

In three of the eight cases doing well the patient's own defences were thought to have contributed significantly. In four, however, residual cavities made the ultimate outlook doubtful. In the seven cases whose organisms developed streptomycin resistance this did not seem to have affected the issue.

Of the five cases doing relatively badly the development of streptomycin resistance was of obvious importance in two and residual cavitation of importance in one of these and in three others. In two cases streptomycin treatment seemed to have resulted in a slight degree of improvement, in two we thought it had perhaps retarded a downhill course, and in one we were unable to attribute to it any significant benefit.

### Discussion

Theoretically there seem to be two possible mechanisms by which strains of tubercle bacilli resistant to streptomycin might appear in the sputum. On the one hand the entire surviving bacterial population might become gradually adapted to growth in the presence of the drug. On the other hand the patient's population of tubercle bacilli before treatment with streptomycin might contain organisms with varying degrees of resistance, the more highly resistant being few in number. Under treatment these would have an advantage over the sensitive strains and might gradually come to replace them.

The first hypothesis presupposes that all strains of tubercle bacilli are initially of equal sensitivity to streptomycin but are capable of gradually adapting themselves to growth in its presence. This adaptation would be most likely to occur if the organisms were exposed to concentrations of streptomycin small at first but gradually increasing. Such conditions would exist if there were parts of the lung, such as cavities, in which streptomycin did not act. Radiating from these areas there would be gradients of antibiotic activity, and strains of tubercle bacilli initially sensitive might little by little grow outwards from the protected areas as they became adapted to higher and higher concentrations of streptomycin. In its pure form this hypothesis is improbable. Not only has such a mechanism been excluded in the development of resistance to penicillin (Luria, 1947) but Pyle (1947) and Davies (personal communication—1948) have shown that strains of tubercle bacilli isolated from the sputum before treatment are not of uniform streptomycin sensitivity, if sufficiently large inocula are used strains highly resistant to streptomycin can be obtained.

If the other hypothesis is correct and streptomycin-resistant organisms come to dominate the patient's population of tubercle bacilli by a process of selection of a few strains innately resistant, we need not presuppose gradients of antibiotic activity. Nevertheless if there were areas relatively protected from the effects of streptomycin, in these the general population of tubercle bacilli would continue to increase and there would therefore be more chance of resistant strains emerging. In addition it might be that gradients of antibiotic activity favoured the growth of moderately resistant strains, and that in these strains selection of highly resistant forms was more likely to occur. Whether such gradients exist is of practical significance, for only if they do is it worth while searching for streptomycin derivatives with a greater diffusibility or a greater activity at low pH.

Fig 4—Relation of degree of streptomycin resistance to clinical progress before resistance occurred. The 'boxes' indicate the groups into which the cases fell.

Fig 5—Relation of degree of streptomycin resistance to mean day of resistance development. The 'boxes' indicate the groups into which the cases fell.

There is no direct evidence that there are gradients of streptomycin activity in certain areas of the tuberculous lung, but observations have suggested that streptomycin resistance occurs more readily under the physical conditions associated with human pulmonary tuberculosis. Streptomycin-resistant organisms are rarely isolated from treated cases of tuberculous meningitis. Of 15 cultures obtained from the Medical Research Council series after the second month of treatment only three showed a rise in streptomycin resistance (Medical Research Council, 1948b). The technique of estimating the degree of resistance was identical with that described in this paper, and in a number of cases the strains were retested by one of us. In guinea-pig tuberculosis treated with streptomycin the development of drug

If bacteriostatic levels of streptomycin are attained within cavities the continuing isolation of sensitive bacilli from the sputum in the early stages of a course of streptomycin might be due to the presence of dormant viable organisms which are coughed up owing to physical factors such as the disintegration of caseous masses. Although streptomycin seems to have a bactericidal effect on a rapidly growing culture at approximately the same level as it is bacteriostatic, it does not appear to be bactericidal to bacilli suspended in a non-nutrient medium (Middlebrook and Yegian, 1946; Garrod, 1948).

There is another factor of possible importance in the development of streptomycin-resistant strains and the assessment of their clinical significance. It may be that strepto-

FIG. 6—Clinical progress before and after development of streptomycin resistance. The figure covers a four months period from the beginning of streptomycin treatment. With Case 89 in which resistance was shown to have developed only on the 189th day, and with Case 90, in which the sputum became negative before resistance occurred, clinical progress in the first two months is compared with that in the second two months.

resistance has so far been reported in only two of the many experiments carried out (Feldman *et al.*, 1947, 1948). The contrasting findings might be due to the existence in human pulmonary tuberculosis of foci of bacilli in caseous areas or cavities less readily penetrated by streptomycin, though in tuberculous meningitis there are often regions isolated by fibrous tissue from the streptomycin circulating in the cerebrospinal fluid (Smith *et al.*, 1948). Another, and perhaps more probable, explanation is that the local aggregates of bacilli tend to be larger in human pulmonary tuberculosis, thus increasing the chance of a resistant strain being present.

There is also some evidence that streptomycin does in fact penetrate cavities. Steenken and his colleagues (1947) found a concentration of streptomycin averaging 77  $\mu\text{g}/\text{ml}$  in fluid from Monaldi drainage, the average blood concentration being 13.3  $\mu\text{g}/\text{ml}$ . In our experience the strain H37Rv is inhibited by about 1  $\mu\text{g}/\text{ml}$  when growing in Dubos-Davis medium adjusted to pH 6, so that it seems likely that the streptomycin concentration in cavities is adequate for bacteriostasis in spite of the acidity of tuberculous pus. It must be remembered that Steenken's figures relate only to a type of cavity suitable for treatment by Monaldi drainage. Schwabacher (1948), however, claims that sputum inhibits the action of streptomycin; in addition it may be that tubercle bacilli are unaffected by streptomycin when growing within cells (Barsky, 1948).

The resistant organisms, on the other hand, would be affected by the patient's defences alone. This differential effect might account both for the late development of resistance in cases doing well initially and, if highly resistant strains were rarer than moderately resistant, for the high degree of resistance found in organisms from patients with poor initial response. Alternatively it may be that the clinical condition is affected, even in the early stages of treatment, by a proportion of resistant organisms as yet insufficient to show in our test.

If, on the other hand, the development of streptomycin-resistant strains is facilitated by gradients of antibiotic activity within the lungs, it may be that the lesions present in those of our patients who showed a poor initial response favour the rapid production of resistant organisms. Our results suggest a possible correlation between the initial degree of cavitation and the time at which resistant strain appeared. The same physical conditions might also favour the evolution of highly resistant organisms, though here we have not been able to demonstrate a correlation.

From this discussion it is plain that at present we can only make tentative suggestions about the mechanism by which streptomycin-resistant strains of tubercle bacilli appear in the sputum of cases of pulmonary tuberculosis under treatment with streptomycin. The problem is perhaps best summarized in the form of questions which still await a definite answer.

1 Are there gradients of streptomycin concentration or antibiotic activity within the lung? If so, do these favour the development of resistant strains?

2 Is there in the tuberculous patient a competition for survival between sensitive and insensitive organisms? In the absence of streptomycin treatment have the sensitive strains any advantage?

3 Do the sensitive bacilli isolated from the sputum in the early stages of a course of streptomycin represent a population actively increasing? If growth has ceased, do the viable bacilli in the sputum represent dormant organisms coughed up owing to physical factors such as the disintegration of caseous masses? What proportion of bacilli seen in a sputum smear are actually viable at different phases of treatment?

4 What is the proportion of resistant tubercle bacilli in the sputum when resistance shows in our tests? What is the proportion of bacilli resistant at the end of treatment, and does this correlate with clinical progress?

5 What is the distribution curve of resistance in the pre-treatment population of tubercle bacilli? Does this vary from case to case, and how does it change during the course of treatment?

The clinical significance of the development of resistance is still uncertain. In only two of our cases was there a clear change for the worse coinciding with the isolation of resistant organisms, whereas resistant strains were obtained from three cases in which cultures subsequently became negative. Other cases continued to improve in spite of the isolation of streptomycin-resistant organisms. In the main M.R.C. series, of which our cases formed a part, a considerable proportion of the treated cases continued to improve after the second month, the mean date of emergence of resistance being the 53rd day. This continued improvement might be due to the streptomycin continuing to act on a residuum of sensitive organisms or to the patient's defences taking over when the streptomycin ceased to be effective.

### Summary

Increased resistance to streptomycin was observed in strains of tubercle bacilli isolated from 12 out of 13 cases of severe bilateral pulmonary tuberculosis treated with 2 g of streptomycin a day for four months or more.

The rise in resistance varied from 4 to over 4,000 times that of the control strain H37Rv. Resistant strains were isolated from the 42nd day of treatment onwards. In the individual case resistance usually rose fairly rapidly to a plateau and then remained at about the same level.

When bacilli persisted in the sputum the numbers at first fell but after resistance had developed tended to rise again.

Streptomycin-resistant strains were isolated from three cases which subsequently became sputum-negative.

The time at which resistance developed and the degree of resistance attained were related to clinical progress before, but not after, resistant strains had been found. In cases which did poorly at first resistant strains were usually isolated early and attained a higher degree of resistance.

The higher the degree of resistance the more rapidly did it appear.

Only two cases showed any great change in clinical course coinciding with the time when resistant strains were first found.

The bearing of these results on the problem of the mechanism of development of streptomycin resistance and its clinical significance is discussed.

We are grateful for the co-operation of the physicians of the Brompton Hospital under whom these patients were admitted, and would like to thank the nursing staff of the hospital for cheerfully sustaining the added burden of work. Dr J. W. Clegg, pathologist at the Brompton Hospital, has given us much help and encouragement, and Miss R. Weitz has done some of the laboratory investigations. This work was assisted by a grant from the Medical Research Council.

## STREPTOMYCIN IN GONORRHOEA

### WITH ITS EFFECTS UPON DARK-FIELD POSITIVE LESIONS OF SYPHILIS

BY

R. R. WILLCOX, M.B., B.S.

Physician in charge of Venereal Diseases Department King Edward VII Hospital Windsor. Senior Assistant Medical Officer Venereal Diseases Department St Mary's Hospital.

In the field of venereology streptomycin has great potentialities which have yet to be adequately explored. It apparently has some action against syphilis, but venereologists hope that this will prove slight, for streptomycin will then assume many of the present indications for sulphonamides in the treatment of venereal diseases in which syphilis is suspect but not proved (Willcox, 1948). Moore (1947) considers that the drug is unlikely to be clinically useful in syphilis, and points to the work of Dunham and Rake (1946), who found that the antisyphilitic effect of penicillin G was 3,000 times greater than that of streptomycin, though Herrell and Nichols (1945) treated four cases of early syphilis with doses of 12–10 g of streptomycin and obtained a temporary absence of treponemata from the dark-field. Herrell (1947) later believed these results to be inconclusive and considered that so far there was no indication that the drug should be used in the treatment of this disease. Fisk and Gruhitz (1946) gave rabbits 1,000–3,000 subtilis units of streptomycin in three divided doses daily for 13–20 days and found no evidence whatever of any antispirechaetal action.

These observations are of considerable interest, for all reports indicate that streptomycin is particularly effective against gonorrhoea. This disease is at present being well controlled by penicillin and there is no clinical evidence of the development of penicillin resistance by the gonococcus on any substantial scale. Many of the suspected cases so far reported have proved on investigation to be due not to the gonococcus itself but to a simultaneously acquired non-specific urethritis (Parkhurst *et al.*, 1947). The possibility that penicillin treatment of gonorrhoea might modify or mask an incubating syphilitic infection has been prominent in the minds of clinicians for some years, and indeed has been responsible for prolonging the period of

surveillance after treatment of gonorrhoea in this country. Such delayed syphilis is not often seen. This matter has been well discussed by Leeming (1947), though Cronin (1947) found little evidence to support this concept.

However, even though the masking of syphilis by penicillin should prove only a minor problem, if streptomycin will cure gonorrhoea in a single dose and at the same time leave the dark-field positive lesions of syphilis untouched it will still have a very definite place in the treatment of gonorrhoea. Especially will this be so in those cases with undiagnosed genital lesions or suspected false positive blood tests, in those persons with gonorrhoea who are known to have had recent intercourse with a syphilitic person, in the re-treatment of relapsing patients who showed Herxheimer-like reactions after the first treatment with penicillin, and in fact in all cases of gonorrhoea in which the risk of existing but undiagnosed concomitant syphilis is greater than the average. It may also be of value in cases in which it is desired that the period of subsequent surveillance should not exceed three months.

Streptomycin is effective against chancroid both in the experimental (Mortara and Saito, 1947) and in the human infection (Hirsch and Taggart, 1948a). In addition, most striking cures have been obtained in granuloma inguinale (Greenblatt *et al.*, 1947a, 1947b, Kupperman *et al.* 1948, Marshak and Rodriguez, 1948, Hirsch and Taggart, 1948b, Barton *et al.* 1947, Zimmerman and Smith, 1948). First reports of its action on non-specific urethritis are hopeful but equivocal (Pulaski, 1947, Kane and Foley, 1947), and my own experience will be the subject of a further paper. The drug has also been widely used in the treatment of urinary infections by Wilson (1948), Schwarz and Lazarus (1947), Keefer *et al.* (1946b), and Finland *et al.* (1946) with upwards of 50% success. In all cases failure seems to be due to a resistance which is very rapidly acquired, but better results, both experimentally and clinically, are obtained in an alkaline medium (Knop, 1946, Kane and Foley, 1947).

Resistance to streptomycin, once acquired, seems to be permanent. Murray *et al.* (1947) found that it continued through more than 100 transfers in a streptomycin-free broth, and Miller and Bohnhoff (1947) noted that two or three transfers in media containing increasing concentrations of streptomycin sufficed to permit the meningococcus to grow in a concentration of 50,000  $\mu$ g of streptomycin per ml whereas no fewer than 147 such subcultures were required for the same organism to grow in a concentration of only 5,000 units per ml of penicillin.

One injection of streptomycin may cure gonorrhoea, and provided the dose is adequate the question of resistance does not arise, though streptomycin-resistant strains of the gonococcus may well appear in the same way as with the sulphamides. Chinn *et al.* (1947) had all of 25 cases of gonorrhoea cured by a single injection of 0.5 g of streptomycin, all of 10 with 0.4 g, and 15 others with 0.3 g. Though three out of five failed with doses of 0.1 g there were only two failures out of 22 treated with single injections of 0.2 g, and toxic reactions were negligible throughout. It is noteworthy that two of these patients developed Herxheimer-like reactions at the time of treatment, and both were later shown to have syphilis. Pulaski (1947) treated nine cases of apparently penicillin-resistant gonorrhoea, and had complete success in seven. The two failures were improved clinically, but the complications of prostatitis and epididymitis were not resolved.

After a single injection of 0.5 g of streptomycin the peak level in the blood is reached within an hour (Molitor, 1947), and effective levels are still present at eight hours.

For continued administration Loewe and Altire-Werber (1947) consider that six-hourly injections should suffice. The drug is excreted in the bile and urine, and may be recovered from the latter (Lamensans *et al.* 1947).

The toxic effects of streptomycin include histamine-like reactions, headache, flushing of the skin, neurological disturbance, vertigo, paraesthesiae, and hypersensitive skin reactions, and there may be an eosinophilia (Keefer *et al.* 1946a). There may also be renal impairment with cylindruria, which is possibly prevented by alkalis. These reactions are not usual after single injections of the drug, and, even with more prolonged administration, McDermott (1947) considers 3 g the maximum safe daily dose. Skin sensitization, developing in a few months in those handling the drug, has also been reported (Strauss and Warring, 1947).

Streptomycin is given intramuscularly in aqueous solution. Preliminary tests have shown no advantages in a peanut-oil-beeswax suspension as with penicillin (Kolmer *et al.* 1946), neither is the action of the drug satisfactory if it is administered orally. However, up to 0.1 g in aqueous solution has been successfully given by the hypodermic (jet injection) (Hirsch *et al.* 1948).

### Case Histories

The following case records confirm the claim that a single dose of streptomycin in aqueous solution is capable of curing gonorrhoea as effectively as penicillin—possibly more effectively—and that the same dose will not adversely influence the dark-field positive lesions of syphilis.

#### Syphilis

*Case A*—The patient, a white man aged 23 had a typical penile chancre of two weeks duration. Characteristic left inguinal adenitis was also present, and the Wassermann and Kahn reactions of the blood were strongly positive. The first dark-field examination was disappointingly negative, but two days later *Treponema pallidum* was visualized without difficulty. He was then given a single intramuscular injection of 0.6 g of streptomycin in 6 ml of isotonic saline, 24 hours later the sore had not altered in appearance and the responsible organism was still readily recoverable.

#### Case 1 Acute Gonorrhoea in the Male

A white man aged 27, the husband of Case 2, was first seen on Sept 11, 1948, with a purulent urethral discharge of three days' duration. Gonococci were observed in the smear and the urine was hazy only in the first glass. He denied other than marital intercourse, which last took place four days previously. The only treatment given was a single intramuscular injection of 0.6 g of streptomycin in 2 ml of normal saline. Two days later the discharge had vanished, smears and cultures from the urethra were negative for the gonococcus, and the urine was quite clear. No gross upset was noted from the injection, though he did comment that when driving his car home from the clinic after the injection he had experienced an odd sensation as if objects were flying past at an abnormal speed.

The following day, however, the discharge recurred though he denied further exposure or the taking of alcohol. His wife (Case 2) was also infected, and both consistently denied any extramarital relations, but the possibility of reinfection cannot be entirely excluded. A week after the first visit the discharge was as profuse as before and gonococci were once again present in the smear. A second dose of 0.6 g of streptomycin (this time in 6 ml of normal saline) was given intramuscularly. No untoward disturbance was noted on this occasion, apart from a transient headache four hours afterwards. The discharge again disappeared within 24 hours. At 48 hours the urine had completely cleared and gonococci were not obtained in urethral smear or culture.

A week after the second injection the findings were still negative and no abnormalities were detectable in the prostate.

dead or prostatic culture. Two days later he was allowed alcohol and protected intercourse with his wife (Case 2), who had also been treated with streptomycin. Actually, unprotected intercourse began the following night, but one, three, and eight weeks later no ill effects were reported by either partner.

#### Case 2 Acute Gonorrhoea in the Female

A white woman aged 27, the wife of Case 1, denied other than marital intercourse, which last took place six days previous to her attendance as a contact, she being quite symptom-free. On examination however, a pronounced urethritis and a cervicitis were found, though erosion was not present. Smears of the discharges showed gonococci in both the cervix and the urethra. She was given a single intramuscular injection of 0.6 g of streptomycin in 2 ml of isotonic saline. Two days later no visible discharge was apparent in either cervix or urethra and, though some pus was still evident microscopically in smears from both sites, no gonococci were observed and none were found on culture.

The patient reported that she had slight pain at the injection site on the day of the injection, and that she had experienced symptoms of influenza two days later. Serum tests for syphilis, however, remained negative in both husband and wife. One week and two weeks later the urethral and cervical smears and cultures were completely free from pus and gonococci, and, as a test of cure for both partners, protected intercourse with her husband was urged. In actual fact unprotected intercourse took place the following night, and this was succeeded immediately by a menstrual period. When seen at the conclusion of this, three weeks after treatment, and again one and six weeks later, the smears and cultures from both urethra and cervix were still negative.

#### Case 3 Penicillin Relapse

This patient, a white man aged 28, was first seen on Sept 6 1948, when he presented an acute gonococcal urethritis of two days' duration which was treated with a single intramuscular injection of 300 000 units of penicillin in oil-beeswax. Five days later there was no discharge and the urine was clear, but on Sept 20 the discharge, which contained an abundance of gonococci, was again profuse, having relapsed four days previously. No history of fresh exposure or alcoholic excess was admitted. He was then given a single intramuscular injection of 0.2 g of streptomycin in 2 ml of normal saline and the discharge disappeared within 24 hours. Nine days later he continued well, the urine was entirely clear, and no gonococci were found in urethral or prostatic smears and cultures. Further prostatic smears and cultures taken two weeks after treatment were also negative.

#### Case 4 Gonorrhoea of Long Standing

The patient, a white man aged 23, developed an acute urethral discharge on July 8, 1948 and gonococci were isolated in the smear. Surprisingly, he left for the Continent the next day without receiving any treatment, and remained untreated until Sept 24 when the discharge was as profuse as ever and many gonococci could be seen in the smear. No complications had developed. He then received a single intramuscular injection of 0.3 g of streptomycin in 3 ml of normal saline. Two days later there was no discharge, and the urine, previously hazy, was now quite clear. The urethral smear showed a trace of pus but no gonococci, and the culture was also negative. Eight days later prostatic smears and cultures gave entirely satisfactory results. He then moved elsewhere, but seven weeks after treatment wrote saying he was well.

#### Case 5 Gonorrhoea Sulphonamide Relapse

This patient, a white man aged 23, was first seen on July 17, 1948 having received 36 g of sulphapyridine over 12 days from his own doctor for a urethral discharge the aetiology of which was never determined. Apart from some dampness of the urethra there was no discharge and the urine was clear. No treatment was advised but he was kept under observation until Aug 28 when he was still symptom-free, the urine being clear and the prostatic secretion free from pus. On Sept 27 he attended with a slight mucopurulent discharge of one day's

duration. He denied fresh contact, yet gonococci were observed in the smear. The urine was still clear, but there were many threads in the first glass. He received a single intramuscular injection of 0.4 g of streptomycin in 4 ml of normal saline. One, two, and seven weeks later there was no discharge and the urine was clear and free from threads, urethral and prostatic smears and cultures were also entirely negative.

#### Case 6 Complicated Gonorrhoea Cowperitis

A negro man aged 30 was successfully treated for gonorrhoea in 1945, in August, 1947, and in September, 1947, when he was given 200,000 units of penicillin. On the last-mentioned occasion he relapsed two days later, developing an abscess of the left Cowper's gland which ruptured exteriorly. On July 29, 1948, he again developed an acute gonorrhoea which was successfully treated with a single injection of 300 000 units of penicillin in oil-beeswax, but five days later the left Cowper's gland was palpable as a small tender nodule and he was given a course of sulphadiazine in addition.

He defaulted from observation, but returned on Sept 29 with yet another apparently fresh attack of gonorrhoea. Gonococci were present in the smear, and the urine was grossly hazy with threads. The left Cowper's gland was just palpable and was acutely tender. It was decided to treat him with streptomycin, though the very small dose of 0.2 g in 2 ml of normal saline was the only amount available. This was given intramuscularly, and when seen 24 hours later the discharge had gone though there was still some urethral dampness, a smear of which showed a moderate amount of pus cells but no gonococci. The urethral culture was also negative; the urine was clear and contained a few threads in the first glass only, and a rectal examination revealed no perineal tenderness.

Though the initial success of even this small dose was truly spectacular, not surprisingly it proved insufficient for two days later the discharge again recurred, and when he attended a week after treatment there was a gross urethral discharge with gonococci present in the smear and a fluctuant left perineal abscess the size of an olive. This was aspirated, some 3 ml of yellow pus being removed, and he was then given eight daily injections of 600,000 units of penicillin in oil-beeswax. Improvement was immediate, steady, and complete, and has been maintained.

#### Case 7 Uncomplicated Gonorrhoea

This patient, a white man aged 43, had a profuse urethral discharge of three days' duration when first seen. Gonococci were present in the smear, and the urine was hazy only in the first glass. Twenty-four hours after a single injection of 0.2 g of streptomycin in 2 ml of normal saline the urethral discharge had entirely disappeared. At 48 hours only epithelial cells were recoverable from the smear, and the urethral culture was also negative. The urine, too, was quite clear and free from threads. After one, two, and five weeks his condition continued to be satisfactory, the prostatic bead was free from pus and no gonococci were obtained in smear or culture.

The gonorrhoea cases, none of which showed any clinical or serological evidence of syphilis, are summarized in the following Table.

No	Type	Sex	Dose	Initial Result	Later Events	Final Result
1	Simple	M	0.6 g	Success	Recurrence after 3 days re treated with streptomycin	Success 56 days
2		F	0.6 g		—	Success 63 days
3	Penicillin relapse	M	0.2 g		—	Success 14 days
4	Protracted gonorrhoea	M	0.3 g		—	Success 49 days
5	Sulphonamide relapse	M	0.4 g		—	Success 49 days
6	Complicated Cowperitis	M	0.2 g		Relapsed after 2 days re treated with penicillin	—
7	Simple	M	0.2 g		—	Success 35 days

## Summary

Seven cases of gonorrhoea (six males and one female) of which six were uncomplicated and one was complicated by *Cowperitis* have been treated with single intramuscular injections of 0.2-0.6 g of streptomycin in an aqueous medium. In all cases the initial response was at least as dramatic as treatment with penicillin in watery or oil-wax media. One patient given 0.6 g apparently relapsed after three days but was successfully re-treated with the same dose of the drug. Another complicated by *Cowperitis*, received only 0.2 g, and after a satisfactory initial response relapsed two days later with abscess formation in the gland and was then treated successfully with penicillin.

One patient with dark field positive primary syphilis was given a single intramuscular injection of 0.6 g of streptomycin and twenty-four hours later *T pallidum* was still recoverable without difficulty from the dark-field.

Apart from possible mild cerebral effects in Case 1 and mild pruritus at the site of injection in Case 2, no toxic effects were recorded.

It is concluded that streptomycin will be of the greatest value in venereology for all cases of gonorrhoea in which syphilis is more than usually suspect. As it appears that its use may not mask an incubating syphilitic infection, it is probable that only a three months post treatment period of surveillance to exclude syphilis will prove necessary for gonorrhoea treated with streptomycin as compared with the six months usual after treatment with penicillin.

LARYNGEAL PARALYSIS ASSOCIATED  
WITH CARDIAC HYPERTROPHY

## REPORT OF FOUR CASES

BY

FRANK T LAND, MB, ChB, DLO, FRFPS

Assistant Surgeon for Diseases of the Ear Nose and Throat  
Western Infirmary Glasgow

The association of laryngeal paralysis with aneurysm of the aortic arch is well known. That the left recurrent laryngeal nerve may be damaged in cases of cardiac enlargement is, however, less well recognized. The paralysis usually occurs in association with mitral stenosis, but recently some instances have been recorded of vocal cord palsy in cases of hypertension with cardiac failure. The present communication is based on four cases of laryngeal paralysis attributable to a coexisting cardiac lesion.

## Case Reports

**Case 1**—A woman aged 26 was examined in consultation with Dr James Richard on account of huskiness of a few months' duration. Laryngoscopy revealed complete abductor paralysis of the left vocal cord. The physical signs in the chest were those of cardiac enlargement and mitral stenosis with incompetence. The apex beat was 4 in (10 cm) from the midline and the right border of dullness was at the right border of the sternum. There was slight oedema of the ankles. Her compensation was fairly good for a quiet life but failed on any exertion. Since the age of 19 she had been troubled with dyspnoea on exertion, palpitations, and oedema of the ankles. At the age of 7 she had had chorea followed by subacute rheumatism, at 10 peliosis rheumatica, at 14 tonsillitis and at 19 subacute rheumatism.

**Case 2**—A woman aged 51 was admitted to Dr George Allan's wards in the Western Infirmary complaining of breathlessness and insomnia for three weeks and also of pain in the left leg and foot. During the previous two years her health had been poor—she was easily fatigued and had slight breathlessness. There was no history of rheumatism or other major illness. The lips and cheeks were cyanosed and there was considerable dyspnoea, which was increased even by speaking. The voice was hoarse. Both ankles were oedematous, the left one being tense and tender. The cardiac rhythm was regular at 150 and the pulse was of poor volume and tension. The blood pressure was 135/100. The arteries were not palpable. The apex beat was diffuse and visible and most forcible to palpation in the sixth interspace at 5½ in (13.3 cm) from the mid sternal line. The borders of cardiac dullness were at the third rib, the mid sternal line, and 5½ in from the mid sternal line. A loud musical murmur replaced the first cardiac sound and was conducted all over the praecordium and into the axilla. The second pulmonic sound was markedly accentuated. Laryngoscopy revealed complete paralysis of the left vocal cord. Examination of the fundi revealed slight arteriosclerotic changes. The patient died three weeks after admission. Permission for necropsy was not obtained.

**Case 3**—A married woman aged 53 was admitted on May 19, 1933, to the Western Infirmary suffering from severe abdominal and left thoracic pain, tachycardia and slight jaundice. She had had cholecystectomy for gall stones in June 1932, but had had recurrent attacks of jaundice during the following winter. The tachycardia was ascribed to auricular flutter, which with digitalis changed to auricular fibrillation and ultimately to regular rhythm. There was no material improvement, pain persisted, and she succumbed to hypostatic pneumonia on July 9. Paralysis of the left vocal cord was observed on laryngoscopy on June 27. The necropsy findings were as follows. The heart weighed 12 oz (340 g). The pericardium was healthy and the left ventricle was of normal size. The left auricle was markedly dilated as were to a lesser extent both chambers of the right heart. The mitral valve was stenosed being 7/10 in (1.78 cm) in diameter. The tricuspid

and arterial valves were healthy and of normal dimensions. The myocardium was somewhat fibrosed. The divided ends of the large vessels were tied off and the heart filled with water. It was noted that the left auricle did not actually impinge on the left recurrent laryngeal nerve, which showed a constriction at the point where, having left the vagus, it passed between the left pulmonary artery and the arch of the aorta. The nerve at the affected point was flattened and much attenuated.

**Case 4**—A man aged 34 was seen in consultation with Dr R. G. Lendrum at the medical dispensary of the Western Infirmary. Five weeks previously his voice had become suddenly weak, and there had been some precordial pain. There was considerable cardiac enlargement, with signs of mitral stenosis, but no dyspnoea or oedema. The patient had had several attacks of rheumatic fever. Laryngoscopy showed paralysis of the left vocal cord.

### Discussion

Before discussing the mechanism of production of the paralysis, the relations of the structures involved require consideration. The left recurrent laryngeal nerve arises from the vagus to the left of the aortic arch on a level with its lower border. The nerve winds below the arch immediately behind the attachment of the ligamentum arteriosum to the concavity of the arch, and ascends to the side of the trachea. The ligamentum arteriosum, the fibrous cord which remains from the closure of the foetal ductus arteriosus, extends from the upper aspect of the root of the left pulmonary artery to the aorta. The relations of the left auricle, pulmonary artery, and aortic arch are shown in the accompanying diagram.

Ortner (1897) advanced the theory that distension of the left auricle produced paralysis by direct pressure on the nerve, and considered that it was supported by the evidence of necropsy in his two cases. Enormous dilatation of the left auricle was found, great enough to produce pressure on the aortic arch and to squeeze the recurrent nerve where it wound beneath the arch. The nerve was completely flattened and atrophied.

Kraus (1900) encountered a necropsy where this theory appeared to be inapplicable. The heart was well compensated, and dilatation of the auricle was insufficient to exert direct pressure on the nerve. He suggested the following explanation. In a well-compensated mitral lesion in which considerable hypertrophy of cardiac musculature has taken place the heart comes to lie more horizontally with its right border on the diaphragm. In such a case the normal bascule or seesaw action is exaggerated. It is thought

that, during systole, traction on the pulmonary artery is forcible enough to pull on the aortic arch through the medium of the ligamentum arteriosum, thereby stretching the recurrent nerve.

Fetterolf and Norris (1911), however, have thrown doubt on the probability of that explanation. They point out that the ligamentum arteriosum runs more or less horizontally, that the arch is supported at both ends, and that it is slung up by its attachment to the cervical fascia. They maintain from their studies of formalin-hardened sections of the thorax that dilatation of the auricle acts indirectly by forcing upwards and backwards the pulmonary artery, which itself is often dilated.

King, Hitzig, and Fishberg (1934) reported three cases of hypertension and arteriosclerotic heart disease with failure of the left ventricle. Coronary thrombosis had occurred in two of the cases, and in all three the left recurrent nerve had been paralysed. They regard the dilatation of the pulmonary artery produced by the engorgement of the lesser circulation as the cause of the compression of the nerve against the arch of the aorta and the ligamentum arteriosum. They conclude that the hypertension in the lesser circulation is an important factor in the production of laryngeal paralysis complicating mitral lesions. The evidence available at necropsy in one of our cases lends support to this explanation, which appears to be the most probable one. Hypertension in the pulmonary artery is a constant feature in mitral lesions before failure of the lesser circulation has occurred, whereas, according to the findings in the limited number of necropsies which have been performed in these cases, the relation of the dilated left auricle or its appendage to the recurrent nerve is very variable.

To judge from the literature, the syndrome is infrequently encountered, and it is to be noted that many of the recorded cases have not been substantiated by necropsy. Since attention was first drawn to it by Ortner in 1897 about 80 cases have been recorded. Osler (1905), however, had seen only two instances and referred to the possibility of confusing aortic aneurysm with mitral stenosis when vocal-cord paralysis also exists. In the systematic examination of 20 cases of mitral disease Ceraulo (1907) found the left vocal cord paralysed in four. Garland and White (1920) reported nine cases collected from the records of the Massachusetts General Hospital during a period of eight years. In a series of 50 cases of advanced cardiac disease with hypertrophy we encountered two with associated laryngeal palsy (Cases 2 and 3), and it therefore seems probable that the condition occurs more often than is suggested by the scarcity of recorded cases.

I wish to acknowledge my indebtedness to my medical colleagues for clinical notes and for the opportunity of examining cases in their wards.

Occupation centres provide for mentally defective children unable to attend school because they are incapable of receiving education there. Local authorities have recently been asked to submit plans for the training of defectives at home and in the centres, and the National Association for Mental Health has recently published an interesting survey entitled "Occupation Centres for Mentally Defective Children" which may serve as a guide to the problem. Detailed information, as well as the pamphlet (price 9d), may be obtained from the National Association at Maurice Craig House, 39, Queen Anne Street, London, W.1.

## PURPURA HAEMORRHAGICA AS A COMPLICATION OF PREGNANCY

BY

J. A. CHALMERS, MD, FRCSEd, MRCOG

*Consulting Obstetrician Northern Counties of Scotland*

Purpura haemorrhagica is generally regarded as a rare but very grave complication of pregnancy. Patterson (1946) collected from the literature reports of 62 cases from 1867 up to the date of his paper. To these he added a further case. He found the maternal mortality was 55%. Mosher (1923) also studied the recorded cases and believed the maternal mortality to be almost 100%, the commonest cause of death being post-partum uterine bleeding. He described the common association of purpura with premature delivery at the sixth to seventh month and noted that infection was usually superimposed. The foetal mortality in his series was in the region of 50%. Rushmore (1925) collected a series in which the maternal mortality was 58% and the foetal mortality 64%. He quoted as typical the case described by Puech in which premature labour occurred at the sixth month and death on the second day of the puerperium from exsanguination as a result of prolonged and persistent uterine bleeding following delivery.

### Clinical Picture

In most of the cases in Patterson's series there was no evidence of purpura before the pregnancy, but haemorrhages into the skin and mucous membranes developed at various times during the course of the pregnancy. In addition epistaxis, haemoptysis, or haematuria may be present. The platelet count is lowered and the bleeding time prolonged. Anaemia is usually present, and there may be a personal and a family history of bleeding, as in Patterson's case. This patient's great-grandmother and grandmother were known to have been bleeders, and her mother, when she herself was born, suffered from post-partum haemorrhage and required transfusion. The patient herself had had symptoms of purpura from the age of 4 and in spite of advice to the contrary had become pregnant. Hess's tourniquet test may be positive. The spleen may or may not be enlarged, and Polowe (1944) described a case of splenoma in which extensive areas of necrosis were present in the spleen.

Pregnancy usually continues uneventfully, and labour may be normal until the third stage is completed, when difficulty may be found in controlling the continuous haemorrhage which tends to occur from the uterus and which may lead to death after some days or perhaps hours. Haemorrhage may take place not only from the uterus but also from lacerations of the cervix, vagina, or parametrium, and haematomata may form deep to the vaginal wall as a result of trauma from the passage of the foetal head or from forceps application. When purpura is present pre-eclamptic toxæmia is particularly dangerous owing to the special risk of placental separation and massive intra-uterine haemorrhage. In this connection Titus (1940) states that some fulminating types of placental separation may be due to purpura.

The bleeding time and platelet count may be normal, but acute attacks of purpura may occur during pregnancy if the platelet count is low. The infant is sometimes affected but, according to Polowe (1944), more commonly it escapes. Siegler (1934), however, has recorded a case where the mother survived but the infant died of haemorrhage. Patterson distinguishes between chronic purpura,

in which pregnancy is a risk so grave that it should not be undertaken, and acute purpura arising during the pregnancy. In the latter type of case, similar to the one described below, complete recovery may take place and the bleeding time and platelet count, together with the other blood findings, may return to normal before the onset of labour, with or without specific treatment.

### Treatment

The treatment most generally advocated is the use of repeated small transfusions of about 200 ml of fresh blood in an attempt to improve the blood's condition. Iron and calcium may sometimes be given with advantage. Vitamin K will often help to restore bleeding and clotting times to normal. Polowe, who quotes a successful case operated on in the eighth month of pregnancy, advocates splenectomy in all cases, but Patterson considers that this should be reserved for those cases in which conservative treatment fails or in which definite splenomegaly is found.

Interruption of the pregnancy during the acute stage is contraindicated, since this will merely open another channel for haemorrhage. Every effort should therefore be made to keep the pregnancy going until the acute stage is over and to improve the platelet count. Delivery should be carried out with as little interference as possible, since the trauma of an instrumental delivery may lead to extensive bleeding in the paravaginal tissues even in the absence of vaginal laceration. Episiotomy and perineal tears are a further possible source of bleeding and should be avoided.

Bleeding at delivery is not usually excessive, but it continues for hours or days afterwards. Patterson recommends that the uterus and vagina should be packed for 48 hours if there is any bleeding after completion of the third stage. At the end of 48 hours the pack should be removed, but it should be reinserted if bleeding recurs and again removed after a further 48 hours. In view of the danger of infection, treatment with penicillin or sulphonamides may be indicated. When bleeding cannot be controlled by other means hysterectomy may be necessary, but there are strong reasons for not operating on these patients if it can be avoided.

As the infant may be affected by the disease a platelet count should be done as soon as possible after birth and the child should be observed carefully for evidence of haemorrhage. If necessary transfusion should be undertaken.

### Prognosis

The very high mortality rate for both mother and foetus shows how serious is the outlook, but in cases of transient purpura complete recovery may take place before labour begins. A distinction should therefore be made between patients in whom the platelet count is low at the onset of labour and those in whom labour follows some time after all evidence of purpura has disappeared. The following case report shows that the condition may be mild and need not give rise to anxiety.

The patient a doctor's wife aged 29 years, was first seen at the 35th week of her second pregnancy, the morning after the appearance of a purpuric eruption on the face, neck, and shoulders. Her first pregnancy had been normal in every respect, and her general health had always been good. There had never been any evidence of a tendency to bleeding. Menstruation was always normal and menstrual loss not excessive. During her pregnancy she had been well, and her diet had been adequate. The day before being seen by me she had vomited some undigested food in the evening but no blood had been noticed in the vomited material. Following this a purpuric rash had been noted on the face, neck, and shoulders. The left forearm gave a positive response to Hess's test, her husband

having taken her blood pressure as soon as the purpuric rash appeared. There was no corresponding rash on the opposite forearm or any sign of bleeding elsewhere. The pregnancy appeared to be normal, the vertex was presenting and the head was well free. Blood pressure was 110/70, and no albuminuria was found.

The patient was brought into hospital, where she was seen in consultation with Professor Stanley Alstead, under whose supervision full blood investigation was carried out. The most significant finding here was a platelet count of 101,500 per cmm—i.e., about 40% of the accepted minimum standard. There were some red blood cells in the urine, singly and in small clumps, and clotting time was prolonged to 14 minutes. In a few days however, without any specific treatment, the rash disappeared and no new ecchymoses were observed. The pregnancy seemed to be progressing normally. There was no evidence of toxæmia, so it was decided to await events. She was discharged from hospital and returned to her home.

A week before term full blood investigation was repeated and appeared to be normal in all respects. The platelet count was 562,320 per cmm and the clotting time 6 minutes 45 seconds. The foetal head was by this time engaged in the pelvis, and the pregnancy seemed to be normal. As a precautionary measure it was decided that she should have a small transfusion of fresh blood at the onset of labour and that vitamin K should be given at the same time. A week later there was a small "show," and a slow transfusion of 250 ml of Group IV blood was given together with vitamin K (1 apilon, 4 ml). A few hours after this labour began, it was completed in about three hours with the delivery of a live female child weighing 8 lb. Immediately after the birth of the shoulders ergometrine, 0.5 mg, was given intravenously and the placenta and membranes were delivered complete without any apparent haemorrhage. There were no lacerations and the uterus contracted well. After the completion of labour bleeding was normal in amount and gave rise to no anxiety. The puerperium was uneventful, and on the fifth day the platelet count was found to be 340,000, the other blood findings also being normal. The child made good progress, being fully breast fed, and did not seem to be affected by purpura, its platelet count on the twelfth day being 346,000. Both mother and child were discharged home in good condition on the 14th day, and subsequent progress has been uneventful.

### Discussion

In 63 previously reported cases of purpura haemorrhagica complicating pregnancy the mortality in both mother and foetus has been alarmingly high, the most recently recorded figure for the former being 55%. The commonest cause of death is prolonged haemorrhage after the completion of the third stage. The case quoted above was mild and transient. Special precautions were taken before and after labour, no undue haemorrhage was observed and the puerperium was normal in all respects. The infant was unaffected. This case confirms Patterson's opinion that there are two different types of case—namely, the chronic, which is associated with all the dangers giving rise to high mortality, and the acute, in which the abnormality may pass off before labour begins and there is no particular danger. The prognosis is good in the acute case unless the acute phase and the onset of labour should unfortunately coincide, but it is not possible to give a prognosis regarding recurrence in a subsequent pregnancy. In view of the very small number of cases recorded it is unlikely that recurrence is common.

### Summary

Purpura haemorrhagica is a rare complication of pregnancy. The literature in which there are records of 63 cases, has been reviewed. A further case is now added.

In the case recorded the purpura was acute and transient, and labour was unattended by any complication.

Treatment should be directed to restoring the blood picture to normal before the onset of labour. If this is impossible special measures for the control of post-partum haemorrhage may be necessary.

The prognosis in the acute cases is good, but there is grave danger of maternal death in the chronic cases.

The foetus is commonly involved, and may die of haemorrhage or of prematurity associated with the early onset of labour in a considerable proportion of these cases.

I am indebted to Dr H J R Kirkpatrick, Dr Elemer Forrai and Dr Edgar Moyes for the blood investigations in this case, and to Professor Stanley Alstead for his advice in the management of it.

## POLIOMYELITIS

### EFFECT OF EXERTION DURING THE PRE-PARALYTIC STAGE

BY

E R HARGREAVES, MD, DPH

Deputy M O H Cornwall County Council

A history of great physical exertion immediately preceding the onset of severe paralysis in attacks of poliomyelitis has often been recorded, but until recently no statistical evidence was available to determine whether such instances were more frequent than chance would dictate. Russell (1947) made a very careful statistical analysis of the degree of physical activity and resulting paralysis in 44 cases of poliomyelitis, and concluded "Physical activity of any

TABLE I—Effect of Physical Activity during the Pre-Paralytic Stage on the Severity of Paralysis in 30 Cases of Poliomyelitis. P indicates onset of Paralysis.

No	Age	Sex	Day After Onset of Pre paralytic Symptoms							Paralysis on Admission	Residual Paralysis at 3 Months

35	35	M	3	2	3	—	—	—	—	C	B
36	21	M	3	3	1	Nil	P	—	—	C	B

Degree of physical activity.—Nil = in bed 1 = not more than ½ day light work (e.g. resting in house with short walks) 2 = Average light work (e.g. secretarial housework school) 3 = Average or heavy manual work (e.g. factory labourer athletic sports)

Severity of paralysis.—A = No paralysis B = No severe paralysis probable recovery to full function C = Moderate paralysis—i.e. moderate multiple paralysis or severe paralysis of a few muscles in one limb D = Bilateral severe paralysis at any level including trunk or gross paralysis of one limb E = Severe and extensive paralysis such as trunk and both lower limbs or severe paralysis of all limbs F = Fatal

kind during the pre-paralytic stage increases the danger of severe paralysis. Complete physical rest in bed during the whole of the pre-paralytic stage seems to protect the patient from severe paralysis."

A similar analysis of cases of poliomyelitis occurring in Cornwall during 1947-8 is shown in Table I. The cases are selected in so far that only those giving a clear history of a pre-paralytic meningeal stage of the illness are included. The standards adopted for the criteria of meningeal involvement, the severity of physical activity, and the degree of paralysis are the same as used by Russell, differing only in that the degree of paralysis in my cases is estimated after three months treatment instead of on admission. Two of the cases (Nos 34 and 38) had travelled to Cornwall by road during the pre-paralytic stage of the illness. In both cases the patient had personally driven his car 250 miles or more.

TABLE II—Showing Maximum Physical Activity in any one Day following First Meningeal Symptoms and Severity of Paralysis

Paralysis at 3 Months	No of Cases	Physical Activity Showing Maximum Activity in 24 Hours			
		Nil (Bed)	Slight	Moderate	Severe
None (A)	9	6	1	2	—
Slight (B)	9	1	3	5	—
Moderate (C)	4	1	3	—	—
Severe (D)	1	1	—	—	—
Very severe (E)	1	1	—	—	—
Death (F)	6	—	—	1	5

Table II shows the maximum activity in a single day and the severity of the resultant paralysis. It will be noted that patients who took to their beds with the onset of initial symptoms proved to be relatively mild cases, six of the ten cases having no residual paralysis after three months of treatment, whereas severe activity in the pre-paralytic stage of the disease led to a very grave prognosis: five of the six fatal cases had undertaken severe mental or physical strain in the days immediately before the onset of paralysis.

TABLE III—Showing Aggregate Physical Activity in Pre-paralytic Stage and Severity of Paralysis

Paralysis at 3 Months	No of Cases	Physical Activity—Total Incidence							
		0	1	2	3	4	5	6	7
None (A)	9	6	1	—	—	—	1	1	—
Slight (B)	9	1	1	3	2	2	—	—	1
Moderate (C)	4	1	2	1	—	—	—	—	—
Severe (D)	1	1	—	—	—	—	—	—	—
Very severe (E)	1	1	—	—	—	—	—	—	—
Death (F)	6	—	—	1	—	—	1	1	3

Table III shows the degree of paralysis plotted against the aggregate of physical activity during the pre-paralytic period. It will be seen that the maximum exertion in any one day is a more important indication of the prognosis than the aggregate of physical activity during the period.

### Summary

The effect of physical or mental exertion during the pre-paralytic stage of poliomyelitis on the ultimate prognosis is analysed in thirty cases of the disease which occurred in Cornwall during 1947-8.

The findings support those of Russell (1947)—namely, that severe physical activity during the pre-paralytic stage is associated with grave prognosis. Severe mental strain such as driving a car over long distances, appears to be equally disastrous, whereas paralysis tends to be mild in cases confined to bed during the pre-paralytic stage.

I wish to thank Dr J G M Molony for granting me facilities to examine these cases during their stay in the County Isolation Hospital.

## Medical Memoranda

### A Case of Tetanus Treated with *d*-Tubocurarine Chloride

The use of curare in tetanus was described by Hunter (1878) and later by Hale White (1901). More recently Florey, Harding and Fildes (1934), Cole (1934), Mitchell (1935), West (1936), Isacson and Swenson (1941) and Cullen and Quinn (1943) using various preparations of curare, were of the opinion that beneficial effects were produced by the use of the drug in this disease. It is felt that the following case history may be of interest now that a derivative of curare (*d*-tubocurarine chloride) is readily available.

#### CASE HISTORY

A lad aged 16 was admitted on April 23, 1948. Pain and stiffness in the lumbar muscles and jaw had started 36 hours previously. Owing to repeated injuries at football the incubation period of the disease is uncertain. On admission his temperature was 97.2 F (36.2 C), pulse 90, and respiration rate 24. His general condition was good and he weighed 8 stone (50.8 kg). On his right shin there was a scabbed sore  $\frac{1}{2}$  in (1.9 cm) in diameter, together with a few scratches. Risus sardonicus and trismus were present, and he was unable to separate his incisor teeth more than half an inch (1.25 cm). There was marked hypertonus of his spinal and abdominal muscles, with slight opisthotonos, and hypertonus of the muscles of his right leg. He was given 240,000 units of antitetanic serum—200,000 units intravenously and the rest intramuscularly. On the day after admission the wound on his shin was excised.

For nine days from the time of admission the patient was kept more or less continuously under the influence of bromethol or paraldehyde. Bromethol per rectum was used for the first three days, an initial dose of 5.1 ml of bromethol fluid being followed by a maintenance dose of between 2 and 3 ml. Following this, paraldehyde, in a 10% solution in saline, was given per rectum for six days in doses of 2 to 4 dr (8-15 g). The frequency of dosage with each drug (about every six hours) was governed by the patient's degree of somnolence. In all, 21.1 ml of bromethol fluid and 57 dr (200 g) of paraldehyde were given.

From the start of treatment, in view of the anticipated prolonged sedation, 5% carbon dioxide inhalations for a few minutes, and coughing exercises, were given six hourly.

During his first night in hospital, and again on the second day when his wound was being dealt with, the patient had a cramp-like exacerbation of his muscular spasm. By the third day his condition had deteriorated in spite of sedation. His body musculature was more rigid, and he was having a good deal of pain. He had a further exacerbation of spasm and was complaining of some difficulty in breathing.

It was then decided to try the effect of *d*-tubocurarine chloride. As we were uncertain of the degree of muscular paralysis which would be required to give relief, we brought to the ward a Drinker respirator and anaesthetic trolley with accessories. *d*-Tubocurarine chloride in solution was given slowly by the intravenous route, and after a dose of 8 mg the patient's face relaxed. He remarked that his muscle pains were quite easier. There was some diminution in the spasm of his lumbar and abdominal muscles, and he was able to separate his incisor teeth 1 in (2.5 cm) compared with  $\frac{1}{2}$  in (0.8 cm) beforehand. Immediately afterwards a further 6 mg of the drug was given by subcutaneous injection. After this we gave *d*-tubocurarine chloride in solution by intramuscular injection in doses ranging from 7.5 to 12.5 mg every few hours, the frequency of administration being adjusted so as to control the pain and exacerbations of spasm. The patient received *d*-tubocurarine chloride for six and a half days at intervals of from two to six hours, the total amount given being 252 mg.

During this time he remained free from exacerbations of spasm and comparatively free from pain, except when the action of curare was wearing off. At these times severe interscapular, lumbar, and abdominal pain would recur, associated with increased hypertonus, cyanosis and a rise in the pulse rate from about 80 to between 120 and 150 a minute.

By the ninth day in hospital the pain, spasm, and cramps were diminishing and we stopped the administration of sedatives and curare. In the ensuing few days the residual stiffness wore off and he felt well and hungry. He lost 4 lb (1.8 kg) in weight during his illness.

On June 20 he wrote to us saying that he felt fit and was back at school.

We are reluctant to draw far-reaching conclusions from the treatment of one case, but we feel that *d*-tubocurarine chloride, when combined with other measures, may find a useful place in the treatment of tetanus.

We wish to thank Dr H Arwel Thomas, medical officer of health for Denbighshire, for permission to publish this case.

### Cardiac Arrest Modified Technique of Cardiac Massage

Cardiac massage has become standard treatment for heart failure during anaesthesia, and a number of lives have been saved thereby. On many occasions, however, the heart does not restart. The following case suggests that a modification of the technique advocated by Hamilton Bailey (1941, 1942, 1946) might be more successful.

#### CASE REPORT

A Bantu woman aged 19 was having a vaginal repair done for a vesico vaginal fistula which she had had for 18 months following a difficult confinement in her village. She appeared to be in a satisfactory condition before the operation. Her heart seemed normal and she was not anaemic.

The operation was performed under gas, ether, and oxygen via an intratracheal tube. It had been in progress about half an hour, during which time there had been very little blood loss, when it was noticed that the oozing from the operation field was dark. This was reported to the specialist anaesthetist in charge, who at once increased the oxygen and stopped the ether and nitrous oxide, but without improvement in the patient's condition the pulse and respiration were fading away. After a few minutes of artificial respiration the anaesthetist reported that the patient's heart had ceased beating, and that cardiac massage was indicated. Meanwhile artificial respiration by means of the anaesthetic bag was continued and an attempt was made to inject adrenaline into the heart. (After cardiac massage had been started it was considered that the needle could not have penetrated deep enough to reach the heart.)

A left subcostal incision was rapidly made and cardiac massage attempted without opening the diaphragm. After a fruitless minute an opening was made in the diaphragm and a thumb was passed through. Massage was then continued for a further eight minutes by rhythmically squeezing the ventricles. This procedure produced no results and the case was considered hopeless.

The hole in the diaphragm was then stretched somewhat and two fingers were passed through. By stretching the diaphragm upwards they could easily reach the upper parts of the heart. Then with some idea at the back of my mind of imitating the path of the normal impulses passing down the bundle of His I stroked the heart firmly in a downward direction. It immediately responded with a weak beat and after a few further strokes it was beating well. Natural respiration restarted shortly afterwards, and within five minutes the blood pressure was 120/85.

The patient, however, did not recover consciousness completely and showed evidence of cerebral damage. She became very spastic and made repeated infantile sucking movements. She would however open her eyes when called by name. Death occurred 30 hours after the heart had restarted beating.

It was felt that if this manoeuvre had been tried earlier the outcome might have been more satisfactory. Perhaps it will prove useful to other surgeons placed in these unpleasant circumstances.

My thanks are due to Professor O S Evans for his advice and

G P CHAPLEWOOD MB FRCSd MRCOG.

Senior Assistant Gynaecologist and Obstetrician,  
Barnsley General Hospital, Barnsley

## Reviews

### ASEPTIC TECHNIQUE

*The Aseptic Treatment of Wounds* By Carl W Walter A B, M D. Illustrated by Mildred B Coddington, A B, M A. Macmillan Surgical Monographs (Pp 372 £2 5s) New York and London The Macmillan Company 1948

Asepsis is to-day so much the atmosphere in which the surgeon has his well-being that few of us spend many moments in thinking actively of its details. Our aseptic technique is so ingrained as to be a form of reflex behaviour rather than an intentional code of conduct. With the advent of chemotherapy, indeed, the miracle of asepsis is largely obscured by what is now the more dramatic miracle of the neo antiseptics. It is a healthy, an instructive, and in some ways a humiliating experience for the surgeon to turn his attention to the full details of the aseptic methods as they are so admirably illustrated in this book, which covers in an almost encyclopaedic way the whole subject of asepsis. It would form an admirable textbook of asepsis for the medical student, it will serve the practising surgeon, however rigid and educated his technique, as a work of reference for numerous details of operating-room technique which are not available elsewhere.

The sterilization of the more modern materials, the packing of sponges and gowns for sterilization, the structure, management, and servicing of sterilizing apparatus, the management of the operating-room atmosphere, and the structure of hospital water supply are only a few subjects which are fully covered and delightfully illustrated by line drawings. The author discusses clearly the distillation and sterilization of water, the cleaning of glassware, and the preparation of fluid for parenteral administration and for blood transfusion, as well as the technique for achieving asepsis in the nursing of infectious fevers. He even considers operating-theatre technique to some extent, and describes the towelling of patients for various operative procedures, and methods of restraining them from breach of asepsis by their own movements. This is a most unusual volume unique of its kind and as a reference work must find a place in every hospital, however small, and in every medical library however specialized.

IAN AIRD

### ENDOCRINOLOGY AND METABOLISM

*The 1947 Year Book of Endocrinology, Metabolism and Nutrition* Endocrinology edited by Willard O Thompson, M D. Metabolism and Nutrition edited by Tom D Spies, M D (Pp 575, illustrated \$3 75 or 21s) Chicago Year Book Publishers, Inc London H K Lewis and Co 1948

This annual review is invaluable for those who have not the time to follow the original literature at first hand and is particularly useful to the clinical endocrinologist, for the endocrine section is written by a clinician by no means lacking the scientific approach. In the section on the pituitary there is a review of the Boston School's demonstration of the *in vitro* inactivation of pituitary thyrotrophic hormone by iodine, due presumably to the formation of an iodo-complex of the hormone, which can be reversed by reducing agents, particularly goitrogenic ones, and an account of the work of Thorn and colleagues showing that adrenocorticotrophic hormone causes (particularly in hypopituitarism but also in normal man) an increase in the urinary excretion of 11-oxysteroids, 17-ketosteroids, uric acid, nitrogen, potassium, and phosphorus, with a decrease in sodium excretion.

A series of papers prove the usefulness of estimating protein-bound iodine in the serum as a reliable index of thyroid function: the low values seen in myxoedema and cretinism being more truly indicative even than the BMR and serum cholesterol. A case of congestive heart failure due to myxoedema and responding to thyroid extract is described. Several papers on propyl thiouracil, which is the form used now in the U.S.A., in cases of thyrotoxicosis are informative. The interesting work of Rawson and McArthur is referred to—namely, on successive biopsies of the thyroid gland in thyrotoxicosis, showing that thiouracil increases slightly the height of the acinar cells, whereas if iodine is given with thiouracil the height is reduced to half its size. Radioactive iodine studies show that thiouracil prevents the thyroid gland from utilizing iodine when iodine

is also given. The authors believe that iodine can cause involution of the thyroid gland of the patient on thiouracil without iodination of the hormone precursor, and that the involuting action of iodine on the thyroid is independent of its iodinating action.

The section on the adrenal gland sets out the most interesting recent knowledge with skill and discrimination. In particular the work of Venning and Browne at McGill University has turned our attention to the high excretion of glycogen corticoids (diabetogenic and anti-insulin) in Cushing's syndrome, and their tendency to disappear in Addison's and Simmonds's diseases. It is no longer sufficient to study only the 17-ketosteroids or androgens and it is hoped that colorimetric methods of assay of glycogen steroids will be added to the assay by glycogen deposition in adrenalectomized rats and help to make the results of these studies more easily available to the scientific clinician. The account of hypertension in children due to pheochromocytoma, their cure by its removal, and the diagnostic test of histamine injection will interest the paediatrician.

The work of an English paediatrician, Professor R. W. B. Ellis, on physiological standards of growth and puberty is rightly considered important to the endocrinologist in the section on the sex glands. Gynaecomastia associated with cirrhosis of the liver and due to inability of the liver to inactivate oestrogens is described. An account of twins with descent of one testis on opposite sides (mirror reflection type) reminds one of two eunuchoid brothers with similar unilateral descent shown by the writer at the Royal Society of Medicine (*Proc. R. Soc. Med.* 1946, 39, 511). The value of biopsy studies in male sterility is indicated. The importance of oestrogens and androgens in the osteoporosis of post-climacteric age and in the healing of fractures at this time should be better known to orthopaedic surgeons. Disorders of menstruation, synthetic oestrogens, and pregnancy tests are widely reviewed as well as masculinizing ovarian tumours. The association of vascular damage, retinitis, and hypertension is discussed as are the changes in mineral metabolism in diabetic coma; there is a wide range of clinical studies in therapy. A case of refractoriness in a young diabetic woman to 5,000 units of insulin in 24 hours is stated to be a record. An account of pancreatic islet cell tumour hypoglycaemia and glycogen disease ends an excellent section on the pancreas. The second section of the book covers the alimentary tract: fat absorption in sprue, folic acid, the haemopoietic system, the cardiovascular system, the brain and nervous system, 'agenized' flour, the genito-urinary system, and dermatology. The whole book is excellently set out and deserves high praise.

S. LEONARD SIMPSON

### DISORDERS OF SPEECH

*L'Aphasie et la Désintégration Fonctionnelle du Langage* By Th. Alajouanine and P. Mozziconacci. (Pp. 156, illustrated, 450 francs.) Paris: L'Expansion Scientifique Française, 23 Rue du Cherche-Midi.

The literature on aphasia is outstanding by reason of the general high level of the contributions. Alajouanine and Mozziconacci's little work is a modest but distinguished newcomer. The authors follow the common practice of considering in some detail the history of the development of our knowledge of speech disorders—an approach which is of particular value in this subject. One or two features in the subsequent chapters will perhaps be unfamiliar to English students. They give due credit to Baillarger's teaching on the dissociation between voluntary and automatic (or spontaneous) utterances. There is a good account of the intellectual level of aphasics and the appropriate methods of investigation by means of non-language tests, and they consider artistic realization in aphasics in a brief but interesting manner. The authors relate aphasia to apraxia and the agnosias, the points of correspondence and of distinction being clearly discussed. One of the most important and at the same time original conceptions in the book is the study of aphasia from a philological viewpoint. Under the term 'syndrome de désintégration phonétique' the authors discuss the elocutionary disorders in aphasia which they believe to have interesting analogies with the first usage of speech in the infant. Seven detailed illustrative case reports conclude this very successful monograph. From the point of view of the student and young neurologist there exists no better clearer or more up-to-date presentation of the subject.

MACDONALD CRITCHLEY

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Liver Injury*. Edited by F. W. Hoffbauer, M.D. (Pp. 95, 51 s.) New York: Josiah Macy, 1948.

Papers and discussion on such subjects as radioactive methionine, portal hypertension, the effect of platinum on the liver and serum lipids in liver disease.

*Sterilisation und Sterile Aufbenahrung von Spritzen und Hohladeln*. By E. Baumann. 2nd ed. (Pp. 120, 7.50 Swiss francs.) Basle: Benno Schwabe, 1948.

A monograph with references on maintaining sterility of syringes and hypodermic needles.

*Income Tax Simplified*. By A. and C. E. Fieldhouse. 19th ed. (Pp. 98, 2s. 6d.) London: Simpkin Marshall, 1948.

A short exposition specially for the business man and student of accountancy.

*The Medical Annual 1948*. Edited by Sir H. Tidy, M.A., M.D., F.R.C.P., and A. Rendle Short, M.D., B.Sc., F.R.C.S. (Pp. 414, 25s.) Bristol: John Wright, 1948.

Articles by various authorities on modern treatment in medicine and surgery, with references to the literature.

*Aetiological Principle of Pyaemia in Ancient Egyptian Medicine*. By R. O. Steuer. (Pp. 36, \$1.50.) Baltimore: Johns Hopkins Press, 1948.

A short study issued as a supplement to the *Bulletin of the History of Medicine*.

*Annual Review of Biochemistry*. Edited by J. Murray Luck. Vol. 17. (Pp. 801, 36s.) London: H. K. Lewis, 1948.

Includes papers on the chemistry of penicillin, lipid metabolism, clinical application of biochemistry and the biochemistry of carcinogenesis.

*Nouveaux Traitements de L'Insuffisance Hépatique*. By J. Cottet and N. Dobo. (Pp. 210, No price.) Paris: Flammarion, 1948.

A discussion of the diet and its constituents required for treating hepatic disorders.

*Der Ausdruck von Stimme und Sprache*. By F. Trojan. Vol. 1. (Pp. 219, Sch. 25.) Vienna: Wilhelm Maudrich, 1948.

An analysis of speech for phoneticians and speech therapists.

*La Spasmophilie de L'Adulte*. By H. P. Klotz. (Pp. 157, No price.) Paris: Flammarion, 1948.

The author describes a syndrome of neuromuscular and mental hyperexcitability with hypocalcaemia.

*Corazon Pulmonar*. By J. Govea. (Pp. 178, \$4.00.) Havana: M. V. Fresneda, 1948.

A monograph on pulmonary heart disease.

*Lehrbuch der inneren Medizin*. By T. Brugsch. Vol. 1. (Pp. 764, M. 40.) Berlin: Urban und Schwarzenberg, 1947.

This volume includes sections on infectious diseases, physiotherapy, disorders of metabolism, and the cardiovascular system.

*The Queen Charlotte's Textbook of Obstetrics*. By Members of the Clinical Staff of the Hospital. 7th ed. (Pp. 572, 28s.) London: J. and A. Churchill, 1948.

This edition includes new chapters on foetal physiology and the rhesus factor.

*Les Varices et leurs Associations Pathologiques*. By L. Gerson. 2nd ed. (Pp. 259, 850 francs.) Paris: G. Doin, 1948.

A clinical account of the treatment of varicose veins and ulcers.

*Critical Studies in Neurology*. By F. M. R. Walshe, M.D., F.R.S. (Pp. 256, 15s.) Edinburgh: E. and S. Livingstone, 1948.

Includes papers on the anatomy and physiology of cutaneous sensibility, the motor cortex and pyramidal tract and the notion of the discrete movement in skilled motion. Reprinted from *Brain* with a lecture on the integration of medicine reprinted from this Journal.

STREPTOMYCIN RESISTANCE IN  
TUBERCULOSIS

The Achilles heel of streptomycin is acquired bacterial resistance. All species are liable to develop this to a degree which renders further treatment quite fruitless, and the rapidity with which it occurs varies with their rate of growth. Resistance has been observed only one day after the start of treatment, and it is quite common among most bacteria within two or three days. The slowly growing tubercle bacillus, on the other hand, has not usually been found to react in this way in less than one month. The frequency, extent, and rate of this change are of vital importance in deciding how to treat tuberculosis with streptomycin, particularly in connexion with the length of the course. In cases of pulmonary tuberculosis the sputum often continues to provide experimental material, and several studies of resistance have been made. Sadusk and Swift<sup>1</sup> found that out of 16 cases, 14, 11, 7, and 6 respectively still had bacilli after one, two, three, and four months of treatment. Only 2 strains had begun to be resistant after one month, after two months, 7 out of 11 were resistant, after three, 6 out of 7, and after four, all 6. The degrees of increase in resistance varied from 5- to over 1,000-fold. These authors were not able to correlate the behaviour of the bacilli with the response to treatment. On p 1009 of this issue Drs J Crofton and D A Mitchison describe a similar study in 13 patients at the Brompton Hospital, the results of which are carefully analysed in an attempt to arrive at such a correlation. In 12 out of 13 patients the bacilli were shown to have increased in resistance, and in two-thirds of them this change occurred within 48 days. With one exception the change was of such a degree that the concentration of the drug attained in the tissues can no longer have been capable of preventing the growth of such bacilli.

Several conclusions can be drawn from the details of these findings. The sooner resistance develops, the greater is its ultimate degree. The amount of clinical improvement during the early stages of treatment is also related to this factor, patients in whom resistance develops late and to a limited extent making better progress. It also appears that the development of resistance is apt to be followed by an increase in the numbers of bacilli in the sputum. On the other hand, the development of resistance is by no means invariably followed by clinical deterioration. 8 patients continued to improve after the change had occurred, 2 continued to deteriorate having been on this road before, and in only 3 was progress arrested or reversed. The authors' discussion of the significance of these facts and of the further questions which arise will be read with interest. As the facts stand they are by no

means unaccountable. There is much to be said for the view that all the good that streptomycin can do is going to be done in six or eight weeks. If at the end of that time the destruction of the bacilli and the resolution of lesions have reached a certain stage improvement may well continue even though continued administration of the drug is having no effect whatever on the surviving bacilli.

It would be useful if further studies of this kind could be pursued on a larger scale, but anyone undertaking them has to face a formidable task. Apart from the ordinary difficulties in working with a fastidious and slow-growing organism a special difficulty in this connexion is the heterogeneity of the bacterial population. There appears to be no doubt that resistant organisms are derived from mutants originally possessing some degree of abnormal resistance, and there may well be small numbers of these in any population. This has been clearly shown by Alexander and Leidy<sup>2</sup> for *H. influenzae* and by Klein and Kimmelman<sup>3</sup> for dysentery bacilli. Vennesland and his colleagues<sup>4</sup> have even shown that the classical strain of *Mycobacterium tuberculosis*, H37Rv, commonly used as a control in tests of streptomycin resistance, includes a minute proportion of cells capable of growth in 100 times the normal inhibitory concentration. Under the influence of streptomycin it seems that individual cells acquire resistance at different rates, and a population develops which includes elements possessing widely different degrees of resistance. Crofton and Mitchison demonstrated this in two of their cases and it is abundantly evident from the elaborate study made by Marjorie Pyle,<sup>5</sup> who repeatedly cultivated the organism obtained from the sputum of patients under treatment on plates of a medium containing seven different concentrations of streptomycin, often obtaining a diminishing number of colonies over a considerable range of concentrations. If such a procedure as this is not adopted it must always be uncertain how far a result reflects the properties of the majority of bacilli in the specimen. Finally, there is some uncertainty about the significance of results obtained with the Davies-Dubos medium. This is delightfully convenient to work with, but according to Fisher<sup>6</sup> one of its constituents, Tween 80, greatly exaggerates the bacteriostatic action of streptomycin on some strains, making them appear sensitive when in fact they are highly resistant as judged by tests in other media. This of course does not detract from the significance of results in which a high degree of resistance has been demonstrated.

It is clear from Crofton and Mitchison's findings that the development of streptomycin resistance is not incompatible with recovery: three out of their cases with resistant bacilli became sputum-negative. On the other hand, it is equally certain, though so far as we know not yet actually proved, that such bacilli if transmitted to another individual would produce disease resistant to streptomycin treatment from the start: there would be none of the benefit obtained in the first patient before resistance had been acquired. This is a very grave danger for the future.

<sup>1</sup> *J. clin. Invest.* 1948 27, 278<sup>2</sup> *J. exp. Med.* 1947 85 329 677<sup>3</sup> *J. Bact.* 1946 52 471<sup>4</sup> *Science* 1947 108 476<sup>5</sup> *Proc. Mayo Clin.* 1947 22 465<sup>6</sup> *Amer. Rev. Tuberc.* 1948 57 69

and the strongest of several reasons for restricting the use of streptomycin to those types of case most likely to benefit from it. The result of making the drug more widely available will be an insistent demand for it from many patients in whom its use is unlikely to have any but a transient effect, and it will be the duty of the profession to resist such demands firmly. To treat a chronic advanced case with cavitation can have little effect but to convert the patient into a much more dangerous source of infection for other people. There is no evidence whatever that a tubercle bacillus—or indeed any other organism—which has acquired streptomycin resistance can lose it again. So far as is known the change is permanent.

## EARLY RISING AFTER OPERATION

To make patients get out of bed a day or two after operation is not a new idea, and though this practice is rapidly becoming more popular there is still considerable opposition to it in many parts of Britain. Emil Ries<sup>1</sup> is reputed to have been the first advocate of early post-operative ambulation in America. His paper was presented at a meeting of the American Medical Association in 1899 and was given a most favourable reception by all the succeeding speakers except one. It is, therefore, rather surprising that Ries's advice was not widely accepted. Perhaps it was because tradition and habit die hard in medicine, and this is especially true of methods sanctioned and advocated by great authorities. In this country we have not lacked distinguished supporters for the therapeutic importance of rest. John Hunter described it as the most powerful aid which the surgeon could bring to disordered tissue, Hugh Owen Thomas stated that "rest must be enforced, uninterrupted, and prolonged", and there are few of us who were not advised as students to read the classical essays of Hilton.<sup>2</sup>

Up to 1939 confinement to bed for ten to fourteen days after a major operation was the usual custom in this country and the United States. Continental practice was more adventurous, and early rising was occasionally advocated in Russia and Germany in a manner which many considered almost barbaric. But shortage of hospital beds during the war and the pressing demands on manpower encouraged a change of view, and there is now a growing and enthusiastic body of supporters of early post-operative ambulation. The majority of patients can readily get out of bed by the third or fourth day after operation, and many of them might with advantage get up even earlier. There is more than historical interest in the fact that Dr Ephraim McDowell, who did the first successful ovariotomy in 1809, found his patient up making her bed on the fifth day after operation.<sup>3</sup>

What are the benefits of early ambulation? First, morale is greatly improved by early rising, and most patients,

having overcome their natural apprehension, are gratified to find how comfortable and fit they are. General health and strength are better maintained, and convalescence is more rapid. Secondly, retention of urine, together with those difficulties associated with the use of the bed pan, is almost entirely obviated, and the work of the nurses is made easier. For patients who are not fit enough to walk to the lavatory the wheeled chair described by Bohmansson and Malmros,<sup>4</sup> which can be pushed over a w.c., is of considerable value. The patient is thereby spared embarrassment and discomfort, while his neighbours avoid those unpleasant odours which are commonplace in hospital wards. Thirdly, as many authors have reported,<sup>5-10</sup> early ambulation diminishes the incidence of post-operative pulmonary collapse, and if collapse does occur it generally resolves more rapidly. Churchill<sup>11</sup> demonstrated an appreciable reduction in the vital capacity after abdominal and hernia operations, while Cutler<sup>12</sup> has shown that the vital capacity returns to normal in half the time if the patient is up and active. As a result of studying the diaphragmatic movements after operation Howkins<sup>13</sup> concluded that so long as the patient had to remain in bed he should be in a comfortable recumbent position with free and frequent movement. Like Spalding,<sup>14</sup> he condemns the Fowler position and advocates early ambulation wherever this is possible. Finally, most workers believe that venous thrombosis and its sequelae are not so likely to occur if early rising is practised.<sup>15-17</sup> According to some reports these complications are lessened tenfold, but most authorities find that the incidence is not reduced by much more than half.<sup>18</sup> It is suggested by others that rising on or after the fourth post-operative day produces little or no diminution in thrombosis and embolism, the greatest reduction in these complications appears to occur when patients get up on the first or second day after operation.

The abdominal surgeon's chief anxiety about early rising has been the integrity of his suture line, and wound disruption and post-operative herniation were much feared. For these reasons metallic sutures, and especially stainless steel wire, have been advocated,<sup>5-19</sup> but operation wounds will heal rapidly and securely even without such desirable aids as non-absorbable sutures. Royster and his co-workers<sup>20</sup> showed that wound healing was as sound in ambulant dogs as in those which had been kept inactive, and Newburger<sup>21</sup> found that wounds healed more rapidly in ambulant rats, thus confirming the earlier work of Kimbarovsky.<sup>22</sup> Experience with human patients supports these findings. There is no published evidence that early rising increases the recurrence rate of inguinal hernia.<sup>23-24</sup>

Contraindications to early ambulation after operation are peritonitis, severe ileus, shock and haemorrhage, cardiac failure, and infective conditions of the legs which preclude

such activity. It is sometimes argued that early rising is undesirable for the tired housewife who needs nothing so much as a good rest in bed. The reply to this is that the housewife need not be strictly confined to bed in order to enjoy a well-earned rest. A very real danger associated with the practice of early rising is the too early discharge of the patient from hospital, this must be strongly resisted. On a number of occasions early discharge from surgical care has been followed by fatal embolism or the development of a "white leg" when the patient was back at home. Some of the undoubted benefits of early ambulation will be lost and the practice brought into disrepute if it leads to neglect of the need for a period of close and careful post-operative supervision. A surgeon would be in a difficult position if he allowed a patient to be discharged on the fourth day after appendicectomy or the seventh day after cholecystectomy (as reported in some American journals) and that patient subsequently developed a fatal embolus in the second week. Although no definite time limit can be set for the development of serious thrombotic complications, it would be wise to keep the patient in hospital for fourteen days after any major operation.

Early ambulation should not be regarded as a procedure to be practised only by surgeons. Patients transferred from a medical to a surgical ward are sometimes found to be suffering from the effects of prolonged bed rest, and it may well be prudent for the surgeon to get such patients up and about for a few days before operation. The dangers of going to bed were described in this *Journal* about a year ago by Asher,<sup>25</sup> who drew attention to the need for changes in wards. Those who recommend early rising after operations will realize the defects of even the most modern hospitals in this respect. There is a serious shortage of comfortable chairs, and most patients would appreciate an adjacent sitting-room or recreation room. Washing and bathing facilities for up-patients are usually inadequate and there is a shortage of lavatories. Those responsible for hospital planning should bear these points in mind when new hospitals are built and existing institutions improved.

## DIET AND THE PRODUCTION OF INSULIN

There have been suggestions that diabetes mellitus is particularly prevalent among those who are accustomed to an unduly generous diet or to consuming large amounts of sugar or fat. While statistics indicate that diabetes is commonly associated with obesity, the evidence connecting its development with excess of a particular food component is less convincing. Thus, while it has been claimed that heavy fat-eaters are frequently affected,<sup>1</sup> it is questionable whether the appetite for fat is developed before or after the pathological changes have begun. Tejning<sup>2</sup> has recently carried out a series of experiments with the object of throwing some light on this important question. He kept groups of rats for about nine months either on a stock diet of rye, meat, milk, and carrots or upon experimental diets rich in carbohydrate, protein, or fat, respectively. The animals were then killed and their pancreases were carefully fixed and freed from adipose tissue. By examining sections cut under carefully controlled conditions and by the application of complicated and laborious mathematical methods

estimates were made of the number, size, and total volume of the islets of Langerhans in the animals of the various groups. Although the insulin contents of the islets were not examined it was assumed, since no pathological changes were found, that the total volume of the islets would give a true indication of the demand made by the diet on the production of insulin.

When the total volumes of the islets were calculated per 100 g of body weight the values for males and females in the group given the natural diet were 0.67 and 0.74 cmm respectively. With the high carbohydrate diet the corresponding values were 0.71-0.89, with high protein 0.59-0.68, and with high fat 0.47-0.50 cmm. If the volume calculated in the group of rats on the natural diet is accepted as normal the diet rich in carbohydrate had little apparent effect on the islets. Their volume, however, was lowered by the diet rich in protein, while the diet rich in fat produced an even greater decrease. Some caution seems necessary in the interpretation of these findings. It is surprising that while the average body weights of male and female rats fed on a diet rich in carbohydrate were 306 and 194 g respectively, weights of only 224 and 168 g were reached with a natural diet. Most workers have found that even when all known vitamins and other nutrients are supplied rats usually grow less rapidly upon artificial than upon natural diets. Further, while the diet high in carbohydrate contained an adequate amount of protein for maximum growth and was well balanced between these types of foodstuff, the diet rich in protein was a "freak" diet containing about 90% of casein. There is some evidence that such a high intake of protein is injurious and the ability of the rats to grow to 227 and 169 g and so equal the performance of the rats upon the natural diet is again hardly what might have been expected. The growth of the rats receiving 76% of their calories as fat to weights of 265 and 194 g calls for the same comment.

It is probably reasonable to accept the hypothesis that the islet tissues respond to dietary changes. It is more doubtful, however, whether the effects of the diets used should be ascribed directly to their richness in carbohydrates, protein, or fats and not to secondary effects on the food consumption and on the general health of the animals. Experiments in which body weights of the rats given the diets rich in carbohydrates and fats could be kept down by restriction of the intake of food to the levels found in the other groups might give useful information on this point.

## ACUTE CORONARY INSUFFICIENCY

Angina pectoris has come to mean an attack of pain in the chest which has a particular quality, site, radiation, duration, and relation to effort, and which is caused by or is closely connected with transient ischaemia of the heart muscle. Cardiac infarction or myocardial infarction signifies necrosis of a substantial segment of heart muscle and is associated with equally well-known clinical features. It is usually but not invariably due to coronary thrombosis. Coronary occlusion, thrombotic or otherwise, means no more than its literal sense implies: it may or may not cause cardiac infarction. So much is clear. What is not so clear is the classification and underlying pathology of those conditions which are neither angina pectoris (as defined above) nor cardiac infarction, but something between the two. Master and his colleagues<sup>1</sup> have proposed the term "acute coronary insufficiency" to describe such cases. The physiological basis for the condition is similar to that

<sup>1</sup> Himsworth H P and Marshall E M *Clin Sci* 1938 2 103  
- *Acta med scand Suppl* 198 1947 128

<sup>1</sup> *J Mt Sinai Hosp* 1947 14, 8  
<sup>2</sup> Wiggers C J *Amer Heart J* 1947 33 633  
<sup>3</sup> Sharpey-Schaefer E P *Brit med Bull* 1944 2 171

for angina pectoris, but the contributing factors may have been present for a relatively long time. For instance, prolonged increase of cardiac work may be due to paroxysmal tachycardia, auricular flutter, hypertensive crises, thyrotoxic crises, and certain drugs, such as an overdose of adrenaline. Prolonged diminution of the coronary blood flow may be due to conditions which seriously lower the cardiac output and blood pressure, such as haemorrhage, shock, massive pulmonary embolism, and vasovagal syncope. Prolonged and relatively sudden interference with the oxygen content of the blood occurs in asphyxia, carbon monoxide poisoning, and acute anaemia. In all these conditions the nutritional demands of the heart may not be adequately met, and subendocardial necrosis in any part of the left ventricle may result. It is believed that the necrosis occurs at this site because of the intramyocardial pressure gradient during systole.

The signs and symptoms may resemble those of cardiac infarction or angina pectoris, but more often they are not quite like either, being too prolonged for ordinary angina yet without many of the features of infarction. Sometimes acute coronary insufficiency is clinically silent. The electrocardiogram shows depression of the RS-T segment in all left ventricular surface leads and therefore usually in all standard leads. The same pattern is common during an attack of classical angina pectoris and may be found in normal individuals when breathing 10% oxygen. Although this conception of Masters has been recognized in some quarters for a long time it is not widely known or accepted, yet there is much to recommend it. Acute coronary insufficiency is believed to be responsible for the occurrence of true heart failure in the later stages of shock<sup>2</sup> and may explain the readiness with which heart failure develops during transfusions in the hyperkinetic stage of severe haemorrhage or anaemia.<sup>3</sup>

### ANTIHISTAMINE DRUGS AND GASTRIC SECRETION

When antihistamine compounds were introduced and found to relieve hay-fever and urticaria, the hope arose that they might be of use in treating hyperchlorhydria, particularly in patients suffering from gastric ulcer, whose gastric juice often resembles the secretion produced by the injection of histamine. This hope has been disappointed, and indeed evidence is accumulating that some of the antihistamine compounds increase the secretion produced by histamine. Emmelin and Frost<sup>1</sup> found that in cats "benadryl" increased the secretion of gastric juice in response to histamine and that in three cats out of four the administration of benadryl alone, without histamine, had a stimulating effect on secretion. Doran<sup>2</sup> observed a large increase in the secretion of free acid in patients given benadryl as compared with the amount secreted without the drug. Benadryl is not a highly specific antagonist of histamine, since it antagonizes acetylcholine as well, this explains the occasional dryness of mouth which it causes. "Neo-intergan" (or "anthisan") has a more specific and stronger action against histamine, and it might have been reasonable to suppose that its effect would differ from that of benadryl. But Howat and Schofield<sup>3</sup> have found that it too acts like benadryl and increases the secretion produced by histamine. Wood<sup>4</sup> has also examined its action in cats and has confirmed Howat and Schofield's findings. The slow intravenous infusion of a mixture of 15 µg anthisan and 5 µg histamine per minute for a period of five hours doubled the volume of juice and rather more than doubled

the amount of free HCl secreted in each 30 minute period. Only when the anthisan was reduced to one-third and the histamine increased four times was there any indication that the secretion of acid was less than with the same amount of histamine alone. It seems that further observations should be made to see whether smaller doses of these antihistamine substances may have the opposite effect to that which has been recorded by all observers hitherto, who, it should be noted, have all used high doses. It is strange that on gastric secretion alone there has till now been no suggestion of antagonism between substances which are antagonists everywhere else. It is likely that there is some simple explanation of this anomaly, which should well repay exploration.

### OVERCROWDING IN MENTAL HOSPITALS

While there has been some recovery from abnormal conditions due to the war, there is still a great deal of overcrowding in public mental hospitals. The report of the Board of Control<sup>1</sup> for 1947 shows that with 128,517 patients in such hospitals there was overcrowding, on the basis of recognized standards, to the number of 14,668. The shortage of accommodation is due to the fact that there has been virtually no building since 1939, to the continuing diversion of some thousands of mental hospital beds to wartime purposes, and to the shortage of nursing staff. The number of beds not in use owing to staff shortage is close upon 2,000, but the shortages are highly localized, and in some parts of the country hospital staffs are nearly at full strength.

The inadequacy of accommodation is more serious than the mere figures suggest, because many mental hospitals have limited admissions to certified cases and have declined to receive voluntary patients—a policy which is clearly detrimental to the whole system of voluntary treatment and causes hardship to persons who voluntarily seek treatment, often in the early stages of their illness, when there is the best prospect of recovery. Nevertheless, voluntary admissions continue to show progress in relation to certified admissions, and last year represented 54.5% of the total. The report states that the health of the patients has been generally good, though there has been a slight increase in tuberculosis (8.8 per thousand, as against 6.5 the previous year and 8.1 as the ten-year average). Among methods of treatment special reference is made in the report to occupational therapy, which has gained wide acceptance in every kind of hospital and is a firmly established form of treatment in mental deficiency institutions for patients of all grades. The report adds, however, that "there are still few hospitals where it can be said that full opportunities are offered to patients as individuals or as members of groups for indoor or outdoor activities which may alleviate illness and point the way to health."

The number of admissions to mental hospitals in 1947 was 46,471. Those discharged recovered or relieved numbered respectively 15,243 and 14,491, 4,002 were discharged not improved and 10,595 patients died. These numbers do not include persons suffering from mental disorder in public assistance institutions and public health general hospitals, or those in receipt of outdoor relief, on whose movements there is no detailed information. Tables are appended to the report with the patients arranged according to class, as private, rate-aided, or criminal, and according to status, whether voluntary, temporary, or certified. The "temporary" patients are very few, only 110 males and 436 females. Rate-aided patients are ten times as numerous as private patients.

## TREATMENT OF ADVANCED RHEUMATOID ARTHRITIS

### A FEW PRACTICAL POINTS

BY

TREVOR H. HOWELL, M.R.C.P.E.D.

Physician, Geriatric Unit, St John's Hospital, Battersea, Lecturer on Problems of Old Age, St Bartholomew's Hospital

The prognosis of advanced rheumatoid arthritis is nearly always described as being bad. The later stages of the disease are often considered as untreatable. In a recent meeting of the Section of Physical Medicine at the Royal Society of Medicine which was devoted to the treatment of this disorder none of the speakers referred to the advanced stages of the disease. Poynton (1931) has said, 'When the atrophic shrivelling of the tissues supervenes, we realize that recovery of the affected parts is not possible'. In fact, most writers use words reminiscent of Dryden

For all the happiness mankind can gain  
Is not in pleasure, but in rest from pain

In the geriatric unit at St John's Hospital, Battersea, a series of patients of this type have been treated during the past year. By means of a combined assault on the disease the team of nurses, physiotherapists, physician, orthopaedic surgeon, and occupational therapist have been able to make some progress in the majority of cases. Several lessons have been learnt, these are put on record here in the hope that they will benefit others.

#### Preliminary Assessment

This is a very important part of the procedure. After a general physical examination a structural and functional survey of the locomotor system is carried out. It has been realized that a deformed joint can be useful and that a few degrees of movement may form a basis for therapeutic exploitation. X-ray reports on the state of the joints are not given great prognostic weight, for many cases with alarming skiagrams have been capable of clinical improvement. All the patients in the unit have several joints affected, so that the question of priority in treatment is an important one. As a general rule it has been the practice to start with the worst non-ankylosed joint. When both arms and legs are involved walking is considered more vital than manual efficiency, but this is not an invariable decision. Where the arthritis is complicated by another disease this should be dealt with first or therapy will be ineffective. Such conditions as renal calculi, gastric ulcers, fibrositis, and various psychological disorders have all caused either temporary or permanent lack of response to anti-arthritic treatment. It is essential to get a good social history, for there are some patients who, on account of domestic trouble or lack of a home, do not want to leave the shelter of hospital. Such patients need help from the almoner, social welfare workers, and others before any great advance can be made. They use arthritis as a shield against responsibility.

#### Procaine Lactic Acid

The injection of procaine lactic acid (P.L.A.) into and around affected joints has been the first line of attack in all the cases treated. The technique has been described elsewhere. A few minutes after injection the joints are manipulated. Some cases benefit most by a sudden jerk, others do better with steadily increasing pressure. There is probably a maximum to the number of joints which can be manipulated at one time. So far I have never done more than seven, but some patients feel faint if more than three are stretched. A great deal depends on the number of adhesions and the state of the joint capsule. Crepitus alone is not an indication that pain is liable to follow. A rubbing or dry grating like that of leather on a glass surface is a warning of pain to come if too much pressure is exerted. Sometimes the sensation experienced as the needle goes into the joint may be a guide. A feeling as of hard nougat is often associated with much pain during the injection, so that the patient finds it hard to relax afterwards. It is thought that this sensation means the puncture of cartilage. Fibrous tissue grips

the needle, is painful on injection, and may hold the point when the syringe is withdrawn. This often detaches needle from barrel and causes patient and onlookers to get a shower-bath. Unless this hard fibrous tissue is properly penetrated the fluid stretches it painfully, so that the patient does not relax fully when manipulated. On the other hand, if the joint cavity has been properly injected subsequent movement is not difficult. Extreme distension of the joint cavity is painful, but is often followed by clinical improvement. Snapping or cracking sounds in a joint which is being manipulated are not always indications of mobility, although they impress the patient. Rupture of an adhesion seems to cause a single noise followed by increased movement. When bleeding has followed injection, post-manipulation pain often lasts longer than normal. Yet this haemorrhage is usually found in joints which are improving so should not be regarded too seriously.

In two cases procaine has been used in place of P.L.A. Diminution of pain, increase of mobility, and decrease of crepitus are less marked in these patients than in those who have the acid injections. Procaine is most useful where dislocation or subluxation of a joint has occurred and where local muscular tender spots are found. In these two instances it seems preferable to P.L.A. A few patients are found who dread the needle-prick and who cry or moan when injected. When this miserable state is pronounced the administration of "allonal" tablets (Roche) 'somniaesels' (Duncan Flochart) or bromide half an hour before the treatment is a useful measure. It is important to have a relaxed and, if possible, co-operative patient to obtain the best results.

#### Treatment

**Physiotherapy.**—In conjunction with the injection therapy physical methods of treatment are also used. Owing to lack of staff and equipment in the chronic hospital which houses the unit, heat was perforce administered only in the form of infra-red rays and of paraffin wax. This was carried out twice a week as a routine, but some patients occasionally had periods of intensive treatment daily for a week or ten days. A few cases had ultra-violet light. Increase of mobility was the patients' primary need, and this was promoted by class-work in remedial exercises. The spirit of competition which this engendered had an excellent effect on the morale of the patients as well as their mobility. The ward sisters visited the classes from time to time. They observed that almost every patient was capable of much more exertion than expected from their usual behaviour. This resulted in making these cases less dependent on help from the nursing staff than previously. I also learnt a great deal from watching my patients doing their exercises. As a guide to the joint most urgently needing treatment this procedure could hardly be excelled, as a measure of the response to therapy it was admirable.

**Occupational Therapy.**—It was realized that manipulation once a week and exercises twice or three times a week would not be enough to maintain any increased mobility in stiff joints. The use of faradism had definite limits in such cases as these, so occupational therapy was encouraged and developed. First of all, knitting was prohibited, for many an arthritic had knitted day in and day out for many years, steadily getting stiffer all the while. Secondly, all forms of occupation were allocated on prescription only. Knitting and basket work for fingers, heavy looms for elbows and shoulders, table looms or leather work for wrists, were tried as a start. Rug-making and toy making have been added, while patients are encouraged to do some of their work in the wards as well as attending the department twice weekly. There is nothing novel in all this, but the results were better than expected in the chronic arthritics who had never done this type of work before and who were depressed from sitting all day in the same ward week after week.

**Orthopaedics.**—The work of the orthopaedic surgeon is a necessary adjunct to the work on chronic arthritic patients, so many of the cases have multiple deformities through lack of adequate treatment in the past. Manipulation, together with serial plasters and other splintage, has done much to remedy the "hopeless" position of so many limbs. When contracted knees have been straightened walking exercises in a machine

or at the foot of the bed can begin. The outlook of the patient is radically altered by such procedures. One danger must be mentioned, however. The bones of most arthritic patients are decalcified and fragile. It is easy to cause a fracture by over-enthusiastic manipulation especially under a general anaesthetic. One problem which has not been solved is that of

deformed fingers with ulnar deviation and some subluxation. The use of paraffin wax followed by faradic stimulation gives some increased mobility, but not very great improvement. A recent development has been the use of springs with Guthrie-Smith slings and a special shoe to allow traction of contracted legs (see diagram). This is giving promising results but is probably capable of further modification and improvement.

### Results

Let us first take the three failures. One patient refused to have injections after a month's experience. Another was improved to the stage of starting to walk after being in bed for two years. Her arthritis was not severe in degree, but she used it as a means of escape from the difficulties of life outside hospital and did not wish to be cured. The third patient was suffering from a psychosis, which became worse during treatment.

As a contrast three patients who were bedridden a year ago are now able to walk and to dress themselves. One, a man aged 70 needed three nurses to carry him to the bath. He had severe arthritis of both shoulders, both elbows, both wrists and hands, the knees were also involved to a less extent. He can now walk, although his knees are still slightly bent. Both shoulders move freely and the elbows have increased flexion. The left wrist has become mobile instead of being fixed in a flexion deformity. The x-ray film shows little change but the functional alteration is immense for the patient can now go to stay with his daughter for a week-end, needing little help to live a normal life.

The man in the next bed had both shoulders, knees, hips, and elbows involved. He had been bedridden for two years before treatment and was also blind. For six months he gave no response to weekly treatment. Then quite suddenly he began to improve. He can now walk a little, dress himself, raise both arms above his head and extend the left elbow better than before. He has learnt to take himself to the lavatory, and consequently needs little nursing attention. The left hip still shows limitation of movement, but this joint has had only a month's treatment so far.

The third patient a woman had also been bedridden for two years. She had both shoulders, elbows, fingers, and knees affected, with considerable limitation of movement. She can now walk and raise both arms level with her shoulders. The elbows retain a slightly flexed position. The left one was manipulated to increase extension, but this procedure resulted in no increase of movement. The area through which the joint moved was merely transferred nearer extension, while a portion of the previous ability to flex was lost. Consequently the patient can no longer do her own hair.

Seventeen other cases have been treated for periods varying from one month to a year. All show some increase of joint movement. One patient whose hands and wrists were involved has been discharged to her home and can do her own housework. Two remain bedridden still but one of these had twenty-six years without treatment before coming to our notice. Both her arms have been mobilized successfully but the legs show great deformity. As she is a frail old woman of 74

the orthopaedic surgeon feels unable to undertake extensive operative treatment. Her neighbour of 60 who was without treatment in bed for twelve years, is improving steadily. Although both shoulders, hands and knees are seriously affected she has recently become able to feed herself after five years, and the knees have now started to flex again. Another woman whose knees appeared to be ankylosed, has just begun to get flexion in them after eleven months of regular weekly injections with P.L.A. It is surprising how often weeks of apparently fruitless effort will suddenly and unexpectedly produce results. At the moment it appears to me that few cases of rheumatoid arthritis are too advanced to benefit from treatment.

### Summary

An account is given of the methods of treatment used for advanced rheumatoid arthritis at St John's Hospital, Battersea.

The results of a year's use of procaine lactic acid are described.

Apart from three patients with abnormal psychology, all those treated in this way have shown some degree of improvement. Several patients who were previously bedridden are now ambulant.

It is sometimes necessary to wait several months before a patient will show response to the treatment.

It is suggested that this therapeutic procedure has improved the prognosis of advanced rheumatoid arthritis.

## OPHTHALMIC SURGERY ABROAD

### FACULTY OF OPHTHALMOLOGISTS

Between the two world wars several visits by groups of ophthalmic surgeons to European and American clinics were organized by the late Percival Hay, of Sheffield, on behalf of the North of England Ophthalmological Society. The idea has been taken up afresh by the Faculty of Ophthalmologists and in the spring of 1948 three parties of twenty surgeons visited Holland, Switzerland, and Paris. The travellers are unanimous in their praise of the courtesy they received at all the centres visited. Instruction and information on special techniques and research were freely given, evidently after careful preparation, and the social side was well catered for.

The party to Holland was organized and led by Mr John Foster, of Leeds. Visits were made to The Hague (Dr Vos), Scheveningen, and the old university town of Leiden where Professor van der Hoeve the doyen of Dutch ophthalmology together with his assistants Drs Copper, Binckhorst, Kok van Wurnig, and Pieck, read several papers in English and demonstrated a corneal graft operation. At Utrecht Professor Weve performed the operations of intracapsular extraction of cataract, diathermy for detached retina, and dacryocystorhinostomy, while Dr Fischer demonstrated the use of a Goldmann contact lens for gonioscopy and showed the museum treasures. At Groningen the emeritus professor Dr Rochat demonstrated his refractometer. Professor Dekking showed a film of a cyclodialysis operation and demonstrated cases of retinitis pigmentosa treated by the subconjunctival implantation of placenta. At Amsterdam Professor Hagedoorn performed two operations and demonstrated an apparatus for measuring orbital incompressibility. Dr Adema read a paper on squint, and some cases were examined showing the late result of corneal graft operations, fiseal lata implants, and resection of the ciliary ganglion.

### Zurich and Geneva

The tour of Switzerland was arranged by Mr Muirhead and Mr Nutt of Sheffield. At Zurich Professor Amsler received the party and lectures were given by Dr Verrey on the findings from puncture of the anterior chamber by Dr Huber on fluorescein tests for investigating the blood aqueous barrier and by Professor Amsler on keratoconus and on detachment of the retina. Practical demonstrations were given on the

subject matter of these lectures, and members of the party examined specimens in the pathological department and saw the work done in the photographic department. Further lectures were given by the Professor on his tests for macular function and his technique for corneal grafts. At Berne Professor Goldmann lectured on gonioscopy and demonstrated his subject on cases. He also showed his perimeter and adaptometer and his new red-free lamp. The Haag-Streit works were visited, and next day the Professor lectured again, this time on the slit lamp examination of the fundus with a contact glass and on the location of non-magnetic intraocular foreign bodies.

At Geneva Professor Franceschetti lectured on keratoplasty, and the party was divided into groups to watch operations and demonstrations. On the following day the Professor and his staff performed further operations, corneal grafting and intracapsular extractions while Professor de Watteville, director of the gynaecological and obstetrical clinic of the University lectured on Some principles underlying dosage of sex hormones. The final lecture and demonstrations were presented by Dr Bamatter, consultant paediatrician of the clinic the title of his lecture being "Clinical and experimental researches on toxoplasmosis."

The journey to Paris was organized by R. J. Buxton. At the Hôpital XV-XX Dr Schiff-Wertheimer, Dr Dollfuss, and others gave a clinical demonstration and later performed ophthalmic operations. Dr Hartmann at the Hôpital Lariboisière presented an interesting demonstration and later showed his technique of intracapsular cataract extraction. Dr Monbrun showed cases of tuberculous choroiditis treated by streptomycin. Dr Favory and Dr Mérigot de Treigny demonstrated ophthalmic operations. A tour of the largest dermatological museum in the world was made and a case of leprosy of the eyes shown. A corneal graft operation was performed at another hospital.

## THE NEW HEALTH SERVICES. ADMINISTRATIVE PROBLEMS PUBLIC HEALTH CONGRESS

A Public Health and Municipal Engineering Congress was held during the third week of November at Olympia. Sessions were arranged under the auspices of the Institute of Hospital Administrators, the National Housing and Town Planning Council, the Women's Public Health Officers Association, the Board of Control and other bodies. Most of the discussions bore upon problems of administration under the new National Health Service.

### The Service Developing

The Congress was opened on Nov. 15 by Mr JOHN EDWARDS, Parliamentary Secretary to the Ministry of Health, who said that the popularity of the National Health Service had led many to suggest that it was overloaded and even in danger of breakdown. "Nothing could be further from the truth. Certainly there have been cases, as the Minister said recently, where frivolous and unnecessary use of the Service has been made. But overall its working has been amazingly smooth, and much according to our hopes and expectations." Mr Edwards mentioned some of the tasks which confronted the Ministry of Health before and shortly after July 5, 1948. He said that 18,165 doctors out of 21,000 were now co-operating in the Service in England and Wales, 8,519 dentists out of 10,000, 5,000 ophthalmic and dispensing opticians, and 14,000 chemists. There were over 40,000,000 people on doctors' lists. Prescriptions were being dispensed at the rate of over 140,000 a year (about the rate expected), about 1,700,000 people had already had dental treatment, and about 1,500,000 people had been supplied with spectacles.

### Communal Health Facilities

In a paper on communal health facilities on housing estates Mr A. R. KERRELL-VAUGHAN gave information concerning

facilities provided or projected on housing estates in various cities. In Birmingham the intention was to establish a health centre under the National Health Service Act in each neighbourhood unit or pair of units, but this policy was not capable of immediate or very early fruition. In Cardiff on each of four new housing estates there was to be a clinic or health centre at a possible cost in each case of £150,000, but here again financial stringency and difficulties concerning labour and materials prevented early materialization of the scheme. At Bristol it was proposed to divide the city into neighbourhood units of about 10,000 population, and communal health facilities were included in the basic planning of all the new housing estates. In Glasgow, in all the housing estates planned by the Corporation provision was made for a community centre where accommodation would be available for local health authority services. At Swansea, on an estate comprising 3,500 houses there was to be a centre with four rooms for doctors use and two for dental services.

A Manchester councillor who took part in the discussion said that in his city the plan was to have 36 health centres and about 75 subsidiary centres. He pleaded for prefabricated construction, so that in ten years' time, if the needs of the locality have altered, it will be easy to replace the health centres. The chief demand made in the discussion was for houses to be allocated to district nurses and midwives on the new estates. Mobile health centres in rural districts were also suggested.

### Hospitals under the New Scheme

Hospital administration in the National Health Service was a subject introduced by Mr GEORGE WATTS, secretary of the Oxford regional hospital board. He described regional hospital boards and hospital management committees as an example of real partnership, each partner having fairly well defined spheres of activity but free to look to each other for help and guidance. As this service was likely to cost £150,000,000 per annum there was bound to be very strict central control and the problem was to reconcile such control with local initiative in the regions. At present those concerned were coping day by day with a vast volume of regulations, directives, and memoranda from the Ministry. Nevertheless, a definite pattern was emerging. The Ministry was telling the regions what they must or might do, and leaving them fairly free within certain limits in the way they did it. Mr Watts asked how far hospital management committees should be left free to carry out certain functions, and how far regional board activities should extend into the field of management. If the regional board decided to delegate the maximum amount of work to management committees it must be even more careful in the selection of such committees. In the Oxford region the management committees were settling down, and the difficulty appeared to be not to get them to work but to prevent them from running away with the bit between their teeth.

Many of those interested in the organization of the hospital service felt that the dichotomy between teaching and non-teaching hospitals was a great mistake. In the great London teaching hospitals there was probably a case for special treatment, but everywhere else the separation was a major blunder and would have to be rectified sooner or later. In the Oxford region the medical advisory committee which the board had appointed, and which included some of the most eminent specialists in the region with a leavening of other experienced persons such as general practitioners, had appointed 14 sub-committees to deal with the different branches of medicine, and this enabled the board to have direct access to the collective wisdom and experience of some 150 specialists and others in the region. It had also given the medical men concerned a real sense of partnership with the board.

### Organization of Psychiatric Services

The prospective mental health services under the new Act were outlined by Dr W. REES THOMAS. It appeared to him that the arrangements for in-patients would be somewhat as follows. Beds would be provided in general hospitals for patients of all kinds who showed no behaviour difficulties and were not otherwise unsuitable. Teaching psychiatric units

would be set up in university centres and would include research departments. Voluntary, temporary, or certified patients would be received in mental hospitals, the average number of beds needed being from 3.5 to 4 per thousand of population. Centres might be established for the treatment of patients suffering from neurotic illnesses; they would be staffed primarily by psychiatrists who would work in conjunction with consultants on the physical side of medicine. Buildings would be set aside for the treatment of old people suffering from the degenerative processes of later life. If existing observation wards in public hospitals were to continue in use they should be staffed and equipped as hospitals or psychiatric clinics able to provide immediate skilled treatment. Beds required in institutions for defectives would probably be 2 per thousand of population. Out-patient departments should be established in general hospitals or psychiatric clinics; mental hospitals were generally unsuitable for this purpose. Separate and special arrangements were required for children needing in-patient treatment. Dr Thomas added that the time when psychiatrists existed only in mental hospitals was long past. He hoped they were on the eve of a new era in which all the medical and social staff of the local authority or of the social agency would be trained to work for mental health.

### Homes for the Old

At a special session arranged by the National Corporation for the Care of Old People Sir ERNEST ROCK CARLING described this problem drawing upon the Rowntree and Sheldon reports and the report of the B.M.A. Committee on the Care and Treatment of the Elderly and Infirm. He said that in 1945, out of the 12,200,000 houses in England and Wales, two million were occupied entirely by persons aged 65 or over. Between six and seven million persons in this country were of pensionable age, and the proportion was rapidly increasing. Although the National Health Service was not directly concerned with the housing of those not in need of hospital treatment, it had a direct interest in the provision made for them. Considerable numbers of beds were filled and the time of many nurses was taken up by people who could be better provided for outside hospital. Geriatric units, if given comparable status to that of paediatric units and charged with continued care of incurable patients discharged to small specialized annexes, would also relieve the severe pressure on beds for acute illness. In time they would eliminate the need for long continued bed rest in a great number of cases so treated to day.

Sir Ernest Rock Carling went on to instance the several different types of hostel and home necessary to meet the phases of ageing and to suit the difference in the educational and nuptial background of the elderly. Speaking of the lowest income groups he said that not many people even now knew the conditions in which the aged had in the recent past dragged out their miserable existence but the sad story had come to light and already after less than a decade, there were very few really black spots left. The task immediately ahead was still further to improve a discreditable state of affairs, but the major problem was to prevent its persistence or recurrence, that was in the hands of the local authorities who had to provide dwellings suited to the physical state and in accordance with the social habit of one-seventh of the population.

On July 1, 1947 I began a new and in all probability the last period of my life. In these words Dr Henry E. Sigerist opens his report to the Yale University School of Medicine. It is reprinted in the Report of the Historical Library 1947-8. Appointed Research Associate in the History of Medicine at Yale University he is now living at Pura, a village ten miles from Lugano, in Switzerland. He had 180 boxes of books shipped across the Atlantic, and in addition he collected 'dozens of large boxes' stored at Basel since 1932 when he went to America. He has now nearly finished three of the four sections that constitute Volume 1 of his *History of Medicine*. This volume is on medicine in prehistoric times and in ancient Egypt and Mesopotamia with a chapter on the medicine of the Hebrews. The volume will include a bibliography of palaeopathology after 1930 and a critical bibliography of histories of medicine. He plans to discuss in Volume 2 the initial phases of medicine in India and China.

## Preparations and Appliances

### ANAESTHETIC APPARATUS FOR CONTINUOUS ADMINISTRATION OF THIOPENTONE AND CURARE SOLUTIONS

Dr R. ATWOOD BEAVER, senior anaesthetist London Chest Hospital, writes: For some time a routine method of anaesthesia for thoracotomy has been the administration of thiopentone and curare via the blood drip. The usual procedure is to puncture the rubber tube with a hypodermic needle, giving divided doses as required. It has been felt that this somewhat unaesthetic procedure results in extremely uneven depth and that continuous administration is preferable.

The simple machine here illustrated has accordingly been developed. It can be made most satisfactorily from the standard blood-bottles, but a neater machine consists of two bottles with flat sides as shown. Pressure is supplied by a hand bulb or, better, from an oxygen cylinder with valve reducing the pressure to 5 lb (2.27 kg) or less. This does not affect the solutions. The mixed fluid is supplied in the ordinary way via a needle strapped into the rubber blood drip tube or on occasion by direct insertion into a vein. The strength of the solutions is such that they can easily be regulated within the desired limits by the pinch-screws. Typical figures are curare 10 mg per 100 ml, thiopentone, 5%. In these dilutions there is no precipitation on mixture. Certain desiderata must, however, be observed:

- 1 The pressure must be sufficient to overcome that of the 'head' of blood from the drip-bottle.
- 2 To this end the area of the rubber stoppers must not be too large or they will blow out.
- 3 The delivery tubes inside the bottles should be prolonged to the bottom by rubber extensions.
- 4 To avoid any risk of air embolism Macintosh type drips should be used but for reasons of clarity they have been omitted from the illustration. If ordinary drips are used the level of fluid should not be allowed to fall below 1 in (18.75 mm) of the bottom of the bottles.

The procedure is to induce with the usual concentrated solutions by syringe and after the preliminaries have been completed to continue by adjusting the drips as required.

For other operations varying solutions may be given, such as thiopentone solution and saline thiopentone solution and adrenaline solution saline and blood.

My thanks are due to Mr T. Holmes Sellors on whose cases the apparatus was developed, and to Dr Roger Wright for his assistance and suggestions.

## Reports of Societies

### BRITISH ORTHOPAEDIC ASSOCIATION

#### ANNUAL MEETING

The annual meeting of the British Orthopaedic Association was held in Belfast from Oct 21 to 23 under the presidency of Mr S A S MALKIN

#### Painful Shoulder

Only pain of intrinsic origin was considered. In an introduction Professor GEORGE PERKINS (London) referred to invariable complete recovery in capsulitis, a generalization denied by subsequent speakers. Mr V H ELLIS (London) found it difficult to fit such conditions as the stiff shoulder complicating coronary disease into a simple classification of extrinsic and intrinsic causes. He described the production of supraspinatus injuries, and pointed out that loss of power in the supraspinatus might be reflex and recover quickly or might be the consequence of a complete tear demonstrable by arthrography. Removal of the acromion facilitated suture of the supraspinatus and hastened recovery. Mr J TULLOCH BROWN (Killearn) had found that in severe cases of the supraspinatus syndrome procaine infiltration was useful in distinguishing patients with loss of movement from spasm, requiring conservative treatment in the first instance, from those in whom structural changes demanded operation.

Mr R J W WITHERS (Belfast) had found 61 cases of capsulitis in 100 cases of intrinsic pain in the shoulder. Two stages might be distinguished: "irritative" capsulitis in which the stiffness was due to spasm and disappeared under anaesthesia, and "adhesive" capsulitis in which stiffness persisted under anaesthesia. The former was treated by rest in a sling, followed by active exercises at the end of about six weeks. "Adhesive" capsulitis demanded primary manipulation followed by exercises. Mr W C SOMERVILLE-LARGE (Dublin) emphasized the value of anaesthesia in distinguishing between muscle spasm and structural change as the cause of limitation of movement. Mr STEWART H HARRISON (Birmingham) had found radiological changes in 30% of patients with pain and stiffness of the shoulder following injury and had found that such cases did not completely recover. Mr F A SIMMONDS (Pyrford) had found in a three-year follow-up that some patients still had slight pain, weakness, and stiffness. Biopsy in the active stage had revealed degenerative changes in the tendinous cuff with a chronic inflammatory reaction but no intra-articular change. The use of a sling and the performance of exercises within the painless range were useful, but he agreed with others that heat was of doubtful value.

Mr J R ARMSTRONG (London) advised excision of the acromion in those patients with the supraspinatus syndrome who did not recover spontaneously. He had found a variety of lesions with similar symptoms: supraspinatus tendinitis, partial and complete supraspinatus tears, calcification in the tendon, and subdeltoid bursitis. Mr G BLUNDELL JONES (Exeter) referred to acute cases of supraspinatus calcification with sudden pyrexial onset, short course, and early dispersal of the calcium deposit. Mr W E TUCKER (London) mentioned focal sepsis and gout as causes of shoulder pain and agreed upon the importance of rest in the acute stage.

Mr C K WARRICK (Newcastle-upon-Tyne) then described three cases of posterior dislocation of the shoulder, and advocated that, unless stereoscopic views could be taken and inspected, the ordinary antero-posterior view should be supplemented by a vertical view with the x-ray tube in the axilla, or a vertical view with a curved cassette in the axilla, or a profile scapular view.

#### Operations on the Hip and Femur

Mr J S BATCHELOR (London) described removal of the femoral head and neck from 50 hips in 44 patients with the object of promoting mobility. In 32 a sub-trochanteric osteotomy also was performed for the promotion of stability. This

might be added to the results of repeated miscarriages treated of the frag way we should like to compare the figures of separate approaches given by Mr Christie Brown

	Malpas	Christie Brown
to ensure its en-		
height skeletal tracings	78.4%	57.8%
spontaneous cure rate	62%	50%
Operation	27%	
ankylosing spondylitis	6%	25%

of the femoral neck, that the psychological effect on the chronic suppurative arthritis that a treatment for six months which 39, unsatisfactory 10, dealt a treatment for six months which instability (3), pain (3), lack should the Fallopian tubes ultimately movement (1), and non-union. There may be so great a variation

induced by one individual in eight weeks after the performance of the operation. In one year, 22% in plasty for osteoarthritis. The dentist before true evaluation of covered with smooth fibrous tissue. H A BRITAIN showed a film of his operation, etc., arthrodesis. Mr H H LANGSTON (Alto M MOORE WHITE of these operations, without sciatic nerve in, FRIEDMANN union in 5, perforation of the obturator 1, 932 graft in 2 and sequestration of the graft in 1 (Oxford) advocated open operation through a position reflecting the gluteus maximus upwards and inwards. had taken place in 16 out of 17 cases. Mr G refractory (Norwich) gave a preliminary communication describing the use of a lag screw in combination with this illustrating the use of a lag screw in combination with this lous grafting in ilio-femoral arthrodesis. Mr JOHN CHAFF the (Manchester) gave an account of preliminary and unsuccessful attempts at arthrodesis by impaction of the tapered femoral head into a hole in the acetabular floor.

#### The Hand

Mr W H GERVIS (Tunbridge Wells) reported 18 cases of arthritis of the first metacarpal carpal joint treated by excision of the trapezium, with good results in all cases of osteoarthritis but with poor results in two cases of rheumatoid arthritis. Mr A DORNAN (Sheffield) had found that conservative treatment gave good results in most cases of Kienbock's disease, so did excision of the lunate (semilunar) bone, even after failure of conservative treatment. Mr GORONWY E THOMAS (Liverpool) had investigated the results of treatment for non-union of the carpal scaphoid carried out three years before. The 28 treated conservatively had done very much better on the whole than 52 patients treated operatively, of whom only 7 were able to return to heavy work. The series were not strictly comparable, however. Backward subluxation indicated a bad prognosis.

A number of other papers were read and Mr NORMAN CAPENER (Exeter) showed a "lively" splint to allow supported movement of the abducted arms in convalescence from infantile paralysis.

### SOUTH-WESTERN REGION SOCIETY OF ANAESTHETISTS

The second annual general meeting of the society was held at Bristol on Oct 29 and 30. Fifty seven members were present, many of them accompanied by their wives. The chief guest was Dr John Gillies, of Edinburgh, President of the Association of Anaesthetists of Great Britain and Ireland, who gave an address on "Spinal Analgesia—its Present Status". Other papers were read by Mr Geoffrey FitzGibbon on "Problems of Anaesthesia for Plastic Surgery," by Dr T B P Wilton on "Anaesthesia for Thoracoplasty," and by Dr R F Woolmer on "The Explosion Risk". Practical demonstrations were also given at the Bristol Royal Hospital and at the Thoracic Unit, Frenchay. An attractive social programme was arranged for the wives of members.

The Chelsea Clinical Society's second dinner meeting of the session was held on Nov 9 at the South Kensington Hotel, London, SW7, with the president, Mr Nils Eckhoff, in the chair. A paper was given by Mr John Hanby on "The Value of Chiropody in Foot Disabilities," and thus stimulated an excellent discussion.

## Correspondence

### Inactivation of Viruses by Heat

SIR—The important communication of Drs H Malmros O Wilander, and B Herner on inoculation hepatitis (Nov 27, p 936) raises the whole problem of the inactivation of viruses by heat. They finally suggest the use of dry heating for routine sterilization of syringes, etc. May I be permitted to submit the result of an experiment in which the effect of moist and dry heating was compared in the case of the virus of vaccinia? One of our sisters at St Bartholomew's had taken service with a mission in Central Africa, and on her leave she sought me out for help about vaccine lymph. The chief disease that they feared at her station was smallpox, which spread there like wildfire among the natives when introduced, and three times over they had found that vaccine lymph coming up from the coast had become inactivated by the heat during its transit.

I was working on vaccinia at the time, and tested the effect of heat on the same virus when suspended in broth in the usual way and when the same specimen had been dried in a desiccator and, after being powdered, resuspended in similar broth. The results were striking. When moist the virus was inactivated completely by exposure for 30 minutes to 65° C, but when dried it not only withstood that amount of heating but even half an hour at 70° C failed to inactivate it, it was not till the same exposure to 80° C was used that it became inert. Before she left I sent the sister some of this dried vaccinia virus, but I never heard if she got it or not.

The great merit of half an hour's exposure to 65° C as a routine is that it can be used easily by having an ordinary covered vaccine-bath such as most laboratories possess. Moreover, should any tubercle bacilli be present they are destroyed, as I have verified again and again by the guinea-pig test with glands removed for biopsy—I am, etc.,

Molsey Surrey

M H GORDON

### The M'Naghten Rules

SIR—I was impressed by the wisdom of your brief comments on the M'Naghten rules (Nov 13, p 882) and am sorry that Dr Clifford Allen (Nov 27, p 955) protests at your "complacent attitude" in a letter which unfortunately is far from showing any real understanding of the matter and its difficulties. His complaint that after the opinion of a competent psychiatrist the issue (of the accused's sanity or insanity) is placed in doubt by the prison doctor's contrary opinion shows that he has not grasped the elementary fact that that issue, just like the issue of a prisoner's guilt or innocence, is a legal problem, not a medical one, and that "Law from Harley Street" is a thing that very rightly has never been, and will never be, tolerated in this country.

Of course the issue is in doubt. That is why it is tried and, fortunately for the interests of justice (and of mercy), the law does not accept the *ipse dixit* of any psychiatrist as a substitute for such trial. I hasten to say that I, for one, should hesitate a very long time before certifying a patient who "stated that his father had been insane and that he himself had impulses to murder children" if that were all I knew about him, and I should greatly like to see the certificate which anyone who attempted the task would produce.

Dr Allen reflects—unfairly and inaccurately in my view—upon the training and experience of prison doctors and proceeds to commit himself to the principle that if a man is medically certifiable he is legally irresponsible. How such a principle could conceivably be accepted by anyone who had spent even a month or two as a resident physician in a mental hospital passes my comprehension.

I have given evidence in many murder trials in two of which the prison doctors were strongly and openly opposed to my view, but in these, as in all the others I received not only absolute fairness but very definite assistance from the judge in my efforts to find a form of words which without sacrificing medical accuracy would express the accused's mental disorder in terms of the M'Naghten rules. I have also had the opportunity of repeated private discussion of these rules with some

of the highest legal authorities in the country, and in consequence I know something of the difficulties and dangers which stand in the way of tampering with them. I am also in a position to confirm most confidently the opinion that they work well in practice and to state that Dr Allen's outline of their working in "case after case" is a travesty of the facts.

Full discussion of this matter, which is so often and so grossly misunderstood by our profession would be unsuitable in your correspondence columns. May I repeat once again however, the elementary point that the function of the expert witness is to assist the court in coming to its decisions. If he is not prepared to let the court conduct its investigations in its own way and to give his evidence without protest in accordance with the rules that the law lays down, then his evidence will be largely valueless and he has no right to appear as a witness at all—I am, etc.

London W1

HENRY YELLOWLEES

SIR—Dr Clifford Allen (Nov 27, p 955) invites the profession to agree that "if a man is medically certifiable he is legally irresponsible." It is to be hoped that this proposition will not be put forward to the legislature as the view of the medical profession, for in my opinion it is quite untrue. I am not a dyed-in-the-wool psychiatrist or psychologist, but I did spend six war years as medical officer in the mental hospital service, and that experience convinced me that a lot of nonsense is written and spoken about irresistible impulses in the insane. Such things do no doubt occur, but only in a small minority. The bulk of the certifiable insane can and do restrain dangerous impulses if they are given sufficient inducements to do so—i.e., if they are under strict, though not of course harsh or inhumane, discipline—I am, etc.,

Tunbridge Wells Kent

HENRY ROBINSON

SIR—About 20 years ago it was a common sight in general hospitals to see police officers sitting by the bedsides of patients who had cut their throats, and suicide was regarded as a crime. Since those days our attitude towards suicide has changed to such an extent that even a suicidal threat is now regarded as sufficient grounds for certification. Alternatively the person may be persuaded to enter a mental hospital as a voluntary patient. In either case the possessors of such impulses are no longer regarded as potential criminals but merely as a danger to themselves.

Perhaps in a further 20 years' time all those who have proved themselves to be a danger to others will also be allowed to live peacefully under supervision in the hospitals provided for that purpose, instead of being prematurely dispatched to another world—I am, etc.,

Lancaster

R PAKENHAM WALSH

### Pre-suppurative Amoebic Hepatitis

SIR—The case reported by Mr C F Critchley (Oct 9, p 681) again raises the question whether an amoebic liver abscess can arise in a patient who has never left this country. From a theoretical standpoint it seems possible though recent literature contains no record of such a case. In Mr Critchley's case such a diagnosis would have been established had *Entamoeba histolytica* been found in scrapings taken during sigmoidoscopy and from the cavity wall at operation—an examination which might profitably be performed in any liver abscess of doubtful aetiology.

Certainly the risk of developing amoebiasis in this country must be increasing with the return of Service personnel from endemic tropical and sub-tropical areas. The cyst carrier rate in ex-Servicemen of other countries has been proved to be far higher than that of the indigenous population (5-10%)—e.g., 20% in Italians,<sup>1</sup> 25% in Germans<sup>2</sup> and 26% in Americans.<sup>3</sup>

Lastly, one wonders whether the syndrome of pre-suppurative amoebic hepatitis exists in this country in ex-Servicemen and could arise *de novo* in one who had never left this country. Although based on sound pathology and long recognized by some clinicians (Brown,<sup>4</sup> Rogers<sup>5</sup>) its indeterminate features make it difficult to diagnose impossible to prove, and in consequence many doubt its existence.

Pathologically the solitary liver abscess is preceded by a diffuse amoebic hepatitis secondary to an intestinal lesion which is usually occult. Military abscesses may then form in the liver and may later coalesce to form the solitary large abscess. Symptoms are vague. Patients generally feel off colour and complain of fatigue after accustomed exercise of slight heaviness in the upper abdomen (e.g., after wearing military equipment), or of feeling less like their usual quota of alcohol. Physical findings are also vague. There may be slight tenderness on heavy percussion over the liver, tenderness of the right acromium ("the liver wing") or of the right trapezius muscle. The liver is generally not palpable, and liver-function tests, sigmoidoscopy, barium x-rays, and stool tests usually reveal no abnormality.

On such slender criteria sceptics may well be forgiven, and diagnoses of functional dyspepsia, hepatitis *sine* icterus, etc., are often made. If, however, such cases are given emetine they make a dramatic symptomatic recovery. This treatment has sometimes, though perhaps ill-advisedly, been given to outpatients without other treatment to which recovery might have been ascribed. Similar cases in England might well be given emetine as a therapeutic test, followed by intestinal therapy for successful cases.

Though proof of diagnosis seems impossible in most cases, perhaps the wider use of hepatic biopsy may bring such cases to light. Once diagnosed, treatment is specific and the development of a large abscess prevented. The condition probably occurs at least ten times as frequently as solitary abscess, and, if Mr Critchley's case represents an amoebic abscess then the possibility of pre suppurative amoebic hepatitis must be constantly considered in patients who have never left the British Isles—I am, etc.,

#### Treatment of the Infertile Marriage

SIR—Mr R Christie Brown's paper (Nov 13, p 851) might encourage the general practitioner to adopt a treatment which has no proper scientific basis. We therefore wish to make a few observations. It has been left open whether his 111 cases "medically treated" were selected or non-selected ones. No patients' ages were given and, more important still, no mention was made as to how many years the patients have been trying for conception, only that all of them had been sterile for more than two years. We accept that all the patients in question had a regular 28-day menstrual cycle, a fact which in itself would not be quite usual if the cases were non-selected.

Does Mr Christie Brown really believe that the success in 13 out of his 38 patients—i.e., 30% of the successes—who have become pregnant one month after the commencement of treatment is due to 0.6 mg of "dienoestrol" and 10 mg "ethisterone" taken daily for not more than 14 days? Is there any explanation why the percentage of successes decreases in the second and third months and reaches its peak six months after the beginning of treatment if, according to Mr Christie Brown, no other than medical treatment alone was given? Or do we take it that the comparatively high figure of successes after six months is due to the fact that investigations were undertaken after three months as well as the medical treatment?

We all know that not all endometria show the same degree of preparation and that it is fallacious to base an opinion on one finding only. There is no record in Mr Christie Brown's article that endometrial biopsies were performed, so that it is difficult to say what percentage of the 38% successful women suffered from incomplete development of the secretory phase. It is difficult to conceive that such a small dose of progesterone taken by mouth can in one, two, or three cycles influence a poorly functioning endometrium.

Oestrone as a sensitizing hormone in the first half of the cycle followed by progesterone alone or in conjunction with small doses of oestrone has been given for a long time by many of us with, unfortunately, disappointing results. Experience has shown that delay in onset of the period could be quite considerable even sufficient to suggest a pseudopregnancy, only to be excluded if a temperature record has been kept.

With regard to the results of repeated miscarriages treated in the same way we should like to compare the figures of Malpas<sup>1</sup> with those given by Mr Christie Brown

	Malpas	Christie Brown
(1) 2 successive abortions	78.4%	57.8%
(2) 3	62%	50%
(3) 4	27%	—
(4) 5	6%	25%

We do not consider that the psychological effect on the patient is good in continuing a treatment for six months which may be entirely misdirected should the Fallopian tubes ultimately be found to be non-patent. There may be so great a variation in any series of cases conducted by one individual in different years (42% successful pregnancies in one year, 22% in another, as analysed by one of us) that a much larger series of cases would be required to be treated before true evaluation of the treatment can be estimated—We are, etc.,

#### Herpes Zoster Treated by Anthisan

SIR—As any severe case of herpes zoster is usually refractory to all treatment and the pain may become well-nigh intolerable I wish to report a case that responded immediately. As this disease is due to a virus with pathological inflammation of the dorsal root ganglia or Gasserian ganglion and as it is the sensory analogue to anterior poliomyelitis and has the same type of lesions in the nervous system and similar cerebrospinal-fluid changes, the same treatment may be worthy of trial in anterior poliomyelitis.

The patient was a well built, very active man of 64 years who presented himself for treatment on account of severe neuralgia affecting the frontal area of the head, the lower jaw, and the occiput on the right side. Very small vesicles were discernible over the supra orbital area only. An anaesthetic local application and analgesics were given. The patient was not seen for two days after the first consultation, when he was again seen on account of very severe supra orbital pain which had prevented him from resting or sleeping for two nights and days. There were large pustules and vesicles corresponding to the supratrochlear and supra-orbital nerves. Oedema was fairly intense and the right eye was closed. There was no involvement of the cornea.

On account of the severe pain not being relieved by the usual analgesics he was given pethidine four-hourly. This gave no relief, and for the next 24 hours he was still in very acute pain and stated that if he had to bear any more he would become distracted. It seemed that he would have to be given morphine. However, it was decided in the afternoon at 3 p.m. to start him on "anthisan," 1 tablet of 0.1 g every four hours. Within one hour the pain had lessened and after the second tablet it had disappeared. Tablets were continued at four-hourly intervals, and he slept all night and all next day, having no pain at all. The oedema rapidly subsided and the pustules and vesicles rapidly healed.

In many cases of herpes zoster pain persists for weeks and even months despite every form of treatment. The above treatment was so immediately beneficial and so dramatic that there is no doubt that anthisan was a specific agent here. "Anthisan" (pyranisamine maleate) is an active antihistaminic agent and has been shown experimentally to possess considerable local analgesic activity. It is stated to be more likely to prove effective in the superficial forms of allergic disorders and in cases uncomplicated by secondary infections and structural changes. In the above case benefit was apparently not due to lessening of oedema and inflammation alone as the oedema and inflammation took 36 hours to subside completely after the first administration. There was probably a specific action on the nervous system and/or the virus—I am, etc.,

Birmingham

MAX HONIGSBERGER.

#### Barbiturate Poisoning and Picrotoxin

SIR—The interesting medical memorandum by Drs R W Bazeley and P H Garrard (Nov 27, p 943) shows again the value of picrotoxin in the treatment of barbiturate poisoning. I agree with the authors that only large doses of picrotoxin are of any use and this fact merits general recognition. With careful observation of the patient picrotoxin overdosage is a remote theoretical danger, the more so as patients in barbiturate

coma can tolerate enormous amounts of picrotoxin. I have used the drug in all cases of coma due to poisoning with different members of the barbiturate group since early in 1946 and have had only one fatality. This was in the case of a woman who was unconscious for longer than 24 hours before starting treatment.

For the drug to have effect it should be given at regular intervals, first by the intravenous route and then by intramuscular injections, it must be persevered with until the first signs of recovery are apparent. Relapses are an indication for a renewal of picrotoxin injections. Nauth Misir<sup>1</sup> treated successfully two cases of barbiturate poisoning with 1,745 mg and 1,024 mg of picrotoxin respectively. However, a total dosage not exceeding 500 mg will be found sufficient in most cases of barbiturate poisoning of marked severity. My own procedure follows the general lines as pointed out by Nauth Misir: the first intravenous injection may range from 6 to 30 mg of picrotoxin, and this is followed 15 minutes later by either more intravenous injections of doses of 6 mg or similar amounts given intramuscularly every 15 or 20 minutes. This treatment is continued day and night until the patient shows signs of coming round. In an article on the subject I have also reported a case of deep coma due to paraldehyde poisoning which responded in a dramatic way to picrotoxin treatment<sup>2</sup>—I am, etc.,

## Prescription of Barbiturates

SIR—'These tablets are dangerous.' This phrase is now so commonplace as a precedent to the News that it appears past comment. Are we right, however, in prescribing in such large quantities a depressing and wit dulling drug such as 'fenobarb' instead of the time honoured aspirin, plain or coloured?

We rightly condemned our Victorian parents for using soothing syrup containing opium to quieten the squalling infant. I am informed by a pharmacist whom I know well that phenobarbitone is now commonly prescribed in doses of  $\frac{1}{4}$  gr (16–32 mg) two or three times a day to infants a few months old and that prescriptions for adults of large quantities of this barbiturate are so numerous as to suggest that half the population is constantly under the influence. Is it not time Sir to reconsider how and when to use these cerebral depressants and to realize that they must be doing considerable harm to the nation?—I am, etc.,

London W 1

T. PEARSE WILLIAMS

## Diagnosis of Tuberculous Meningitis

SIR—The introduction of streptomycin in the treatment of tuberculous meningitis renders the early and correct diagnosis of this disease of even greater importance than in the past. I would therefore like to draw attention to the significance of the glucose content of the cerebrospinal fluid in this condition.

The fact that a low value is found is of course well known but the highly specific nature of this finding seems to have escaped attention. I have notes of 65 cases of tuberculous meningitis examined in the laboratory of the Belfast City Hospital in all of which tubercle bacilli were demonstrated in the cerebrospinal fluid and in which the cells, protein, glucose and chloride content were estimated. On classifying these cases the following figures were obtained:

Glucose in mg. per 100 ml	Number of Cases
40–50	2
30–40	10
20–30	18
under 20	35

It will be seen that in only 2 out of 65 cases was the glucose value above 40 mg per 100 ml, in 53 it was under 30 mg per 100 ml and many of the cases described as 'under 20 mg' showed the merest trace of glucose. I would also point out that this fall in glucose is an early sign: sometimes 2 or 3 spinal punctures were necessary to demonstrate tubercle bacilli but the glucose was always low from the first though falling still lower as the case progressed. It is well known that

in other cases of non-purulent meningitis—e.g. poliomyelitis, benign lymphocytic meningitis, cerebrospinal syphilis etc.—the glucose content of the fluid is normal, a fact which has been repeatedly confirmed in this laboratory. The chloride content, though often lowered, does not show the same invariable fall and is not reliable in the diagnosis of tuberculous meningitis.

I am now so convinced of the specific value of a low glucose content that I have no hesitation in basing a diagnosis on this fact alone in the presence of a pleocytosis of the lymphocytic type. If the value is below 40 mg per 100 ml the diagnosis is highly probable; if below 30 mg per 100 ml it is certain. On the other hand a value over 50 mg per 100 ml practically excludes the disease. I therefore put forward a plea for the more general adoption of this test in the diagnosis of tuberculous meningitis—I am, etc.,

Belfast

J. T. LEWIS

## Intravenous Procaine in Transfusion

SIR—With reference to the medical memorandum on this subject by Drs G. S. W. Organe and C. F. Scarr (Oct 30 p 787) I found during the war that venous spasm indicating fairly severe shock, was quickly overcome by rapid transfusion of a liberal volume of blood or plasma, using positive pressure. Other important points to be noted are:

(1) Obstruction to the flow of blood into a vein is usually due to blood clot in the leads or needle of the blood giving set, and is relieved by replacing one or both of these.

(2) Vasoconstriction of the vessels supplying the vital medullary centres—the apparent cause of shock—may not necessarily be overcome by replacement of a volume of protein fluid equal to the volume of blood lost; this explains why transfusion of large volumes may be necessary.

(3) This vasoconstriction is mechanically, but entirely temporarily overcome by lowering the head end of the patient. Therefore in case of shock that is apparently fully resuscitated in the head low position will often require transfusion of several pints more when raised to the horizontal position.

(4) Shock is a major cause of death in abdominal wounds and operations, and since the head low position is found to be effective in the treatment of shock the use of Fowler's position post-operatively must cause a multitude of deaths. Penicillin and sulphonamides not being available to prevent peritoneal infections it remains for some courageous surgeon to treat his abdominal operation cases rationally in the horizontal position post-operatively, having given at the same time liberal transfusion—i.e., six to twelve pints (3.4–6.8 litres)—of protein fluid.

(5) If this is done it may be necessary to give intravenous saline post-operatively only when the gut has to be kept at rest.

(6) Vigilant observation of the respiration rate during transfusion is necessary in abdominal cases to prevent pulmonary oedema, as, in marked contrast to limb-wound cases, the pulse may remain poor after adequate transfusion or even when pulmonary oedema has occurred.

(7) Liberal transfusion so improves a patient's morale that genuine neurotics might benefit remarkably by small transfusions (perhaps three pints) of protein fluid.

—I am, etc.,

London W 14

A. D. MILNE

## Justifiable Laminectomy

SIR—I was interested in Dr J. C. W. Hopkins's memorandum entitled 'An Unusual Trophic Ulcer' (Nov 20 p 905), but a little surprised at his conclusions. Having practically proved that his patient has a prolapsed disk at the lower end of his spine causing a trophic ulcer in his foot, he proposes to leave the *font et origo malorum* alone and merely "intensify" the local treatment to the ulcer. This ulcer will almost certainly get worse as the cause of it has not been removed and a man of 29 is being condemned to numbness of the heel and thigh and at the very least, a progressive ulceration for the remainder of his life. From my experience as an ordinary GP I would make a guess that within a year or so other and far more serious neurological symptoms will occur possibly if bladder complications supervene resulting in the death of the patient. May I take two illustrations from my own practice?

1. Foundry worker, aged now about 44, discharged from the Services in 1942 for sciatica and lumbago, probably caused by a prolapsed spinal disk. I could get no orthopaedist to tackle his spine.

but he got great relief from 6 months in a plaster jacket. As soon as this was taken off his pains came back. Eventually a skilled orthopaedist decided to deal with the cause, and about 9 months ago he did a laminectomy and removed a prolapsed disk. Since then the patient has had no pain and has gone back to work.

2. Farm labourer, aged about 40. In October, 1942, he developed slight loss of power in both legs, a symptom which increased rapidly. There was weakness of the left hip and knee, loss of left lower abdominal reflexes, and flexor plantars. W.R. and Kahn were negative. He was then discharged and sent home no better. In April, 1943, I sent him to London, where he was thoroughly tested in two famous neurological centres. Pressure paraplegia, due to either an intramedullary or extramedullary tumour, was the verdict. In favour of the former was the Brown-Séquard syndrome of the stronger right leg being the more analgesic. The upper limit of the analgesia faded away gradually from D 12 to D 10. CSF in April, 1943, pressure 100, jumping up briskly on jugular compression, thus excluding spinal block. (Queckenstedt) W.R. negative, total proteins 35 mg per 100 ml. Histamine test meal showed plenty of free acid, thus excluding P.A. Lipiodol injection high up in spine showed on x-ray no evidence of spinal block. Everything being negative, he was sent back to me again with instructions to 'carry on with his work as well as he could'. By now he was staggering along on two sticks.

In September, 1943, I sent him to another hospital, as I felt sure, though entirely ignorant, that a laminectomy was the answer. His CSF then showed 55 mg of protein. It was proved later that there was, in fact, spinal block in this case, though manometry did not show it. Increase of CSF protein below the level of the block, or cord compression, is part of From's syndrome and is probably due to compression of the spinal veins. As a result the pressure within these veins rises and consequently blood corpuscles and plasma containing much protein exude. By July, 1944, the plantar reflexes were extensor, but Queckenstedt's test was still negative and there was no evidence of block. Dorsal fluid showed cells 9 per ml and protein 30 mg per 100 ml. But in the lumbar region the cells were 1,500 per ml and the protein 225 mg per 100 ml. At long last, in July, 1944, a laminectomy was done, and between D 11 and D 12 a large, hard, prolapsed, calcified intravertebral disk was found and removed. The cord below it was grossly atrophied for  $\frac{2}{3}$  in and displaced to the right. But it was too late. On July 15, 1944, he had a violent haematuria and collapsed and died the next day. Post mortem examination confirmed the operative findings and showed a gangrenous cystitis.

There is no doubt in my mind that if a laminectomy had been done two years previously the life of this hard-working skilled and conscientious farm expert could have been saved. The ordinary G.P. is left wondering: (1) What are the risks of laminectomy? Surely they could not include the death of the patient if the spine was found to be normal? (2) Why do not physicians, if paralysis increases and the patient's condition deteriorates in spite of all negative spinal findings insist on laminectomies?—I am, etc.,

### Peptic Ulcer in Pregnancy

SIR—The excessive rarity of symptoms of peptic ulceration during pregnancy has been stressed by all authorities, and the interesting case reported by James (1948) is therefore a warning that one should be on the look-out for such cases. The fact that though rare the disease is often fatal is all the more reason to pay serious heed to continued symptoms of dyspepsia during pregnancy especially where the patient is a known sufferer from ulceration of the stomach or duodenum.

Bralow Scheinberg and Necheles (1948) have just recorded four more cases from Chicago. Perhaps only one of these could strictly be reckoned a complication of pregnancy in that the patient who was known to have had a duodenal ulcer eight years previously suffered from epigastric pains during the whole term of her pregnancy. Her symptoms entirely disappeared as soon as the pregnancy terminated, nor had they reappeared since, even during a second pregnancy four years later.

There are three main groups of theories to account for the rarity of peptic ulcer in pregnancy—the mechanical, the chemical and the hormonal. As already mentioned by James Hurst was the first to suggest that the rising uterus supported a lax stomach and so induced a better blood supply in the lesser curvature. Both in James's case as well as in one cited by Mulsow and Brown (1936) the major accidents took place at a time when the stomach could not have been lifted much higher—in the later weeks of pregnancy.

Balint (1927) first suggested a general tendency towards increased alkalinity in tissue fluids during pregnancy, and other observers have confirmed that with increased alkalinity there is found a hypo- or even achlorhydria, especially in the first six months of pregnancy, thereafter the acid values began to rise towards normality and might even reach supernormal figures in the puerperium in certain cases.

Crohn (1927) and others noted that peptic ulcers tend to break down in the puerperium. Winkelstein (1940) thought that the agent responsible for the breakdown might possibly be prolactin, the lactogenic hormone of the anterior pituitary. During gestation the formation of prolactin is inhibited by the high blood-levels of ovarian and placental hormones. He made experimental studies on animals with chemically produced peptic ulcers by treating them with the ovarian hormone theelin. The response was good and the ulcers healed within ten days. Abrahamson, Church, and Hunter (1942) treated peptic ulcers in human beings with theelin, and, while getting a slightly better immediate response as compared with a number of controls treated on routine lines, found the long-term results no better.

Of these three theories, then, that of hormonal control would appear to be the most probable. It was seen above how the mechanical theory was apparently disproved by the occurrence late in pregnancy of major complications of ulcer. The chemical theory would appear to be at fault in the following case.

### CASE REPORT

There is at the moment in my wards a woman 34 years old who is suffering from a relapse of ulcer symptoms and whose barium meal three weeks ago showed the presence of a duodenal ulcer. The cause of the present relapse was sought in her personal history, and it is quite reasonably ascribed to the fact that she and her mother-in-law have to live under the same roof. From the age of 18 she had suffered from slight, vague, windy indigestion, to which she paid little heed. In 1943 she was married and later that year became pregnant.

At about the second month of pregnancy she got a bad fright. A kettle of boiling water fell over her sister's foot, the patient witnessing the accident. She has, she says, always reacted strongly to any family accident, having lost her voice on two previous occasions of mishap. On the night of this accident the patient went to bed with a pain in the epigastrium such as she had not previously felt, and she vomited. In such state she continued for the next 36 hours until the pain suddenly became intolerable, and she was admitted to this hospital as an acute abdomen. At operation a perforated peptic ulcer was found and repaired, and the patient's post-operative and subsequent gestational progress was completely uneventful.

Wild surmises of having stumbled across the first case of 'psychogenic' Curling's ulcer were dispelled by the operation notes (Mr G W Duncan) which revealed that not only was the ulcer prepyloric in position—incidentally the commonest position in which a simple benign ulcer perforates—but it appeared from the surrounding induration to be chronic.

Another case was that of a woman of 41 admitted on Aug 25 suffering from severe hypochromic anaemia. She gave a history of intermittent dyspepsia since the age of 24, when she had a severe haematemesis and was ill for the next eighteen months. She had no further trouble until she became pregnant at the age of 28, when she vomited blood on several occasions during her pregnancy and had ulcer pain for a number of weeks. The pregnancy came to a successful conclusion and was followed by a slow return to normal health. For the next seven years the patient was symptom free until, in 1943, she was admitted to Hillingdon Hospital with a recurrence of ulcer pain and haematemesis. Barium meal showed a duodenal ulcer, and six months later, on re x-ray, a small ulcer was still seen. In 1944 she became pregnant again and once more ulcer pain and haematemesis recurred. The pregnancy terminated successfully. Since 1944, every six months there have been recurrences of pain and haematemesis. During her present admission she had irregular pain and some tenderness. A barium meal a month after admission failed to show any ulcer. There was no evidence of splenic anaemia or other blood dyscrasia at any time.

## Treatment of Varicose Ulcer

SIR—I was much interested in Dr S M Rivlin's letter (Oct 16 p 723). I have been treating varicose ulcers since 1928 and my clinic numbers about fifty ulcer patients per week and some thirty or forty cases of varicose veins. I have improved and varied my own technique very considerably as the years have passed and I have watched and noted with interest all other suggestions for the healing of ulcers such as high ligation, multiple division or tributaries, excision of veins, and even lumbar sympathectomy.

One is driven back to the conclusion that ulcers of the legs are due fundamentally to the forces of gravity. The legs become congested either with old age (wearing out of the rubber elastic of the vein walls) or because of varicose veins. I feel most emphatically that the first essential in the treatment of a gravitational or varicose ulcer is tight compression and bandaging of the ulcers and tight bandaging of the lower leg. It is necessary of course to obliterate those veins with retrograde downward circulation which add to the congestion.

I myself get a very high percentage of cures by appropriately placed sites of injection of veins combined with the choice of an appropriate sclerosing fluid in each case, and above all by compression of the injected strip of vein after injection by elastic adhesive strapping applied over the vein.

My own technique in the cure of ulcers consists in putting zinc stearate or sulphamylamide powder into the ulcer base, then covering up the ulcer with "jelonet," applying calamine powder around the ulcer if there be any associated redness of the skin, then bandaging the whole leg from the toes to below the knee with "ichthopaste," placing external to this a pad of wool or sponge rubber over the ulcer site sometimes in a pyramidal manner and then finally elastic adhesive strapping put on from above downwards to prevent rucking up by the stocking, combined with a brick stirrup underneath this strapping.

Once the leg has been freed from its oedema it can be kept in this condition by the wearing of an elastic stocking or better still, by an "elastolex" bandage, the latter being an improvement on "elasto crepe" for it has some strands of rubber fibre in it. As the months pass the leg resumes its normal proportions, owing to sclerosing of veins in certain cases, and the patient can sometimes abandon all support for the leg.

Recurrences of ulcers in fat old and middle-aged women are due to the lack of after-care in not keeping these legs supported. Admittedly I had about 5% of out patient failures. I used to hospitalize these failures and give them open dressings. Certain cases even of these failed, but I succeeded in getting them ultimately healed by putting them to bed with the occlusive dressings above described. Finally I must add that I have recently had some very gratifying results in the small percentage of resistant cases by putting them to bed and treating the ulcers with 'vacutan' fluid.

One cannot emphasize too emphatically that destruction of given veins by any or all methods does not take away from the patient the tendency to have and develop other varicose veins and it is only by appropriate tight and occlusive bandaging that ulcers can be healed and can remain healed—I am, etc.

STUART MCAUSLAND

## Pensions for Diabetics

SIR—Those who like myself take an active interest in the pension struggles of the war disabled and of war widows cannot but be disturbed by the attitude expressed by Dr R D Lawrence in his letter Pensions for Diabetics (Nov 13, p 874). It would seem to close the door finally on all claims involving diabetes.

Dr Lawrence's book *The Diabetic Life* has long been the mainstay used to support these claims at tribunal hearings and High Court appeals therefrom. Now the supports have been cut away by the author himself. To this end he is recanting the phrase, 'When shares go down in Wall Street diabetes goes up' and no doubt the interrelated sentences commencing, 'There is also a large nervous element in diabetes' will be expunged as well. Is one to gather from Dr Lawrence's letter that heredity and previous obesity are the only recognized causes of the disease and that the numerous other factors mentioned in his book—infectious diseases, mumps, diseases of the liver, etc.—must now join nervous tension in the dustbin of discarded factors? As a matter of logic worry may be excluded as a cause because 'otherwise the majority of humanity would become diabetic,' but it would be equally

logical to exclude the possibility of non purulent meningitis—e.g. poliomyelitis. The cases of pytic meningitis, cerebrospinal syphilis, etc.—the complications may be of the fluid is normal, a fact which has been rather than lack of acid in this laboratory. The chloride content, the article by Drs and does not show the same invariable fall (July 24 p 194) dealing the diagnosis of tuberculous meningitis in diabetes mellitus of the specific value of a low glucose thus afflicted and war of hesitation in basing a diagnosis on disease that diabetes is presence of a pleocytosis of the lymphocytoid or support? is below 40 mg per 100 ml the

With commendable frankness, if below 30 mg per 100 ml in chapter on Causation" in a value over 50 mg per 100 ml thus 'To the majority of cases I therefore put forward a diabetes I have to answer that I am of this test in the diagnosis, this of itself will be sufficient to, etc., any reasonable doubt to which they warrant—I am, etc.,

J T LEWIS

## Marxist Genetic Transfusion

SIR—Dr C D Darlington's "review memorandum on this Lysenko's pamphlet, *Soviet Biology* see F Scurr (Oct 30) lamentably short of the standard of objectivity spasm indicating a scientific journal. The reviewer gives no hint of rapid transfusion criticisms of contemporary biology. I remember positive pressure my first M.B. that evolution is due to mutations 'due to chance'. When I began to read about, usually due to membranes I remember how odd the doctrine seems set, and is germ plasma is independent of the soma, though the separated by membranes of greater or less permeable medullary Lysenko's Marxism leads him, as it does, to deny the over inadequate doctrines so much the better for Marxism, to the

Dr Darlington does not even indicate that Lysenko of larger tend to establish links between germ plasma soma and ment. He does not mention his experimental work. Therefore before a he strays from the exact subject of the book he is slow to be reviewing he does not indicate what is emphasized when example by Professor Eric Ashby, that in Russia the peas have so far lost their traditional conservatism (which and restricts development in our own dominions and colonies) they welcome Lysenko's innovations with enthusiasm.

I do not presume to argue about biological theory but I can see plainly that Dr Darlington's review is not intended to give readers a chance of knowing the issues. I only conclude that it was written with a political purpose, it was "pure propaganda," and therefore that it was much suitable for the sensational newspapers than for the *British Medical Journal*—I am, etc.,

London SE 24

H M R

SIR—Dr Ashley A Robin's letter (Nov 27, p 955) Marxist genetics makes strange reading. I certainly would be interested to see a report of the speeches of Lysenko's at the Russian congress and I would be even interested to know if the opposition was pre-arranged or if it were genuine what happened to the opponents of Marxist genetics at the conclusion of the congress. I wonder if Dr Robin has seen the letter from Sir Henry Dale in *The Times* of Nov 26 announcing his resignation of the honorary membership of the USSR Academy of Science and making special reference to Lysenko. According to Sir Henry, 'Lysenko's own claims and statements make it clear that his dogma has been established and enforced by the Central Committee of the Communist Party as conforming to the political philosophy of Marx and Lenin. Dr Robin styles himself not as a geneticist but as one who can read.' Might I respectfully suggest that he read some more—I am, etc.,

London W 4

JOHN C C LANGFORD

## Glamorous Labels

SIR—The section of our profession concerned primarily with the conflict between man and his total environment rather than with the unfortunate results thereof seems determined to pour that good old wine hygiene, from a multitude of new bottles bearing such eye-catching and glamorous labels as social medicine, human biology, human oecology or, in the utility and less stylish ranges, preventive medicine and public health.

but he got great relief from 6 months in a plaster as this was taken off his pains came back. Even age such thrusting orthopaedist decided to deal with the cause and, but hygiene despite he did a laminectomy and removed a prolapsed al desires of VD prophylaxis has had no pain and has gone back to vendors, remains for me 2 Farm labourer, aged about 40. In October 1943 and of the enhancement slight loss of power in both legs, a symptom seems to cover the whole. There was weakness of the left hip and therefore I would like to see abdominal reflexes and flexor plantaris of these subjects enunciated negative. He was then discharged and in other words, what are their April, 1943, I sent him to London, where in two famous neurological centres either an intramedullary or extramedullary appreciate an agreed table of. In favour of the former was the fact by this fraternity. In reaching stronger right leg being the more must be purged of vague political analgesia faded away gradually from loose-thinking—in fact, cleansed of 1943 pressure 100, jumping up with woolliness in expression which excluding spinal block (Queckenberry) prominent feature in the thought disorder 35 mg per 100 ml Histamin.

thus excluding P.A. Lipiodol, the highest authority is itself an offender. X-ray no evidence of spinal disease. The Ministry of Health for the year ended sent back to me again with the principles of the World Health as well as he could. B 109, the principles of the World Health.

In September, 1943 declared. The first two are "Health is a though entirely ignore physical, mental, and social well-being and C.S.F. then showed absence of disease or infirmity," and, "The was, in fact, the highest attainable standard of health is one show it increased mental rights of every human being, etc" (my or cord compression immediately present themselves (1) What within these estions immediately present themselves (1) What plasma contains absence of disease or infirmity? One cannot leave reflexes were logical vacuum (2) When, in fact, is disease or there was a really absent except in a state of complete physical, and physical and social well-being? (3) If health is a complete were 1,500, how can one reach the highest attainable standard of it? in July, 1943, Gowers says in *Plain Words*, "It is a sign of D 12 a lay thinking to qualify words that have an absolute and remain."

and disagree. he had short, the laudable fashion for plunging excitedly Post in the virgin jungle of health would be followed more show factually by the man at the periphery if those already admitted to this pastime appeared to know of each other's stance, to have correlated their plans of campaign, and to be taken the same language when broadcasting their situation. The reports—I am, etc,

of Morden Park Surrey DENIS H D BURBRIDGE

### Jelly-fish Stings

SIR.—The interesting letter from Dr Frank R. Neubert (Nov 6, p 839) on the subject of jelly-fish stings recalls a paper on this subject published by Stuart and Slagle. These authors point out that, contrary to popular belief, the sting of a jelly-fish can be extremely dangerous, even fatal, and add that the effects are usually much more serious in tropical waters. They give the following description of the symptoms:

"Pain of a burning character at the site of contact, with redness followed by an urticaria like weal about 10 minutes later, muscle spasms before the rash is well established, involving most of the skeletal muscles and sometimes mainly in the extremities, a flushing of the skin, moderate dilatation of the pupils, congestion of the respiratory mucous membrane, a profuse, thin, mucous nasal and bronchial secretion, profuse lacrimation in severe cases, incessant cough with expectoration, spasm of respiratory muscles, leading to difficult respiration, and probably accounting for the patient's fear and anxiety which is frequently thought to be hysteria, and marked pain in the abdomen and back, where large muscle groups are stony-hard with spasm."

Wade reported the case of a patient who died from suffocation within a few minutes of being stung on the lower extremities, although he had never been submerged. There was visceral congestion and status lymphaticus.

As treatment Dr Neubert used tincture of *Urtica urens* with apparent success though it seems possible that the first sting may have conferred an immunity against subsequent ones. He gave morphine by injection and states that the native remedy was sugar internally and vinegar externally. Stuart and Slagle (loc cit) describe two patients who were stung by a "Portuguese man-of-war." In addition to an urticarial rash both men had severe muscular cramps, great difficulty in breathing and oppression of the chest. Each was given an intravenous

injection (10 ml) of 10% calcium gluconate, with almost instantaneous relief of the dyspnoea and muscle cramps.

Apparently nothing is known about the nature of the toxic substances, although the above authors state that it is injected by means of tiny barbs which are contained in thousands of trigger hairs on the tentacles and which protrude on contact. The urticaria, the extremely rapid onset of generalized symptoms, and the equally rapid action of calcium injections certainly suggest an allergic reaction, but there is an opportunity for an interesting piece of research here analogous to the recent investigation of nettle stings.—I am, etc,

## POINTS FROM LETTERS

### Plain Words on Nursing Shortage

Mr L H HORNSBY (Ministry of Labour and National Service) writes of Mr W S Brindle's comments (Oct 30, p 800) one word *Touché*

### Breast feeding

Mrs V BENNETT (London, N 8) writes. I think Dr Rachel Pinney (Nov 13, p 878) has made a very valuable point in suggesting that one of the major causes of lactation failure is outside interference in the tender emotional partnership of mother and newborn baby. I was a practising midwife for many years, and since my marriage and the birth of my own two children I have taken several private maternity cases. I did so on the understanding that the mothers under my care allowed the breast-feeding to be conducted after my own method, which is simplicity itself. Immediately after the birth and washing (the mother being fit enough) the baby is put to the breast, where usually it takes hold and gains comfort enough to sleep cosily in the crook of its mother's arm. A cot stands by the head of the bed so that, if the mother wishes, the sleeping baby can be put down within her reach. Both usually sleep for an hour or two. When the baby next awakens and cries it is again given to the mother with the instruction to give it the breast if it appears to be mouthing around for food. I find this feeding can be conducted in a semi-recumbent position, it being necessary for the nurse only to assist in making the pillows comfortable and supporting. This goes on day and night, with the baby regulating its own feed times and sleeping all the time between. Before three days the baby seems well satisfied with the colostrum it receives and even goes three or four hours without attention. I find there is very little breast engorgement on the third day, and I have never had a breast abscess from over-congested breasts or a failure to feed the whole nine months. The baby, needless to say, is relaxed and happy and never cries unless hungry or cold.

### Fumes and Colds

Dr T H DURRANS (Bourton-on-the-Hill, Glos) writes. I have read with interest the letter from Dr G C Pether (Nov 13, p 879), and I think it may be of interest to him and other doctors to relate an experience covering over thirty years. In a chemical factory with which I was concerned we made among many other chemicals products from sulphur dioxide, and the air in the plant buildings where these sulphur dioxide products were made was always heavily charged with the gas. It was continuously found that the workmen in this plant were markedly free from the common cold and from "influenza." It therefore seems probable that the presence of sulphur dioxide in the saliva for periods of 8 hours or more daily has a protective effect. It should be noted that other workmen working in parts of the factory remote from the sulphites plant did not enjoy the immunity.

### Tendon Rupture and Rheumatoid Arthritis

Dr PETER LONDON (London, S W 15) writes. Dr G D Kersley's report (Nov 27, p 942) of the spontaneous rupture of a deep flexor tendon in a patient suffering from rheumatoid arthritis prompts me to report a similar experience of my own in a woman of 66. In this case, however, rupture was traumatic, being due to the patient's jabbing petulantly at a push button on her radio set, though such a stress seems inadequate as a cause of rupture of a normal flexor tendon. In her case the tendon was the deep flexor to the right middle finger, it was explored, as her left hand was almost useless and she was anxious to regain if possible fuller control of the digit. Rupture had occurred just proximal to the digital synovial sheath and as there was no sign of fraying of the tendon it must be assumed that rupture was due to some other sort of weakness. Simple suture was carried out, but the amount of movement regained was very small.

## Obituary

### J H SEQUEIRA, MD, FRCP, FRCS

Dr James H Sequeira, who was for many years consulting physician to the Skin Department of the London Hospital, died in Kenya at the age of 83. He had a world wide reputation as an authority on diseases of the skin.

James Harry Sequeira was born in London on Oct 2, 1865, and educated at King's College School. Entering the London Hospital with a science scholarship in 1884, he qualified in 1889, graduated MB in 1890, and proceeded MD a year later. He was a dresser to Mr Frederick Treves, as he was then and he was also much influenced by Sir Stephen Mackenzie, whose house-physician he became. He took the FRCS in 1893, the year in which he won the Hutchinson Prize and he was elected FRCP in 1905. Dr Sequeira studied at Vienna some years after qualifying, and subsequently he worked under Niels Finsen in Copenhagen. He was responsible for translating Finsen's book on phototherapy in 1901, and at the London Hospital, where he was appointed assistant physician in 1902, he set up a light therapy department which was the first of its kind in this country. He also wrote at this time some of the early reports on the treatment of epitheliomata by x rays and radium. In 1905 Dr Sequeira published *An Elementary Treatise on the Light Treatment for Nurses*. His well known textbook *Diseases of the Skin* appeared in 1911 and reached a fifth edition in 1947. Dr Sequeira was for many years editor of the *British Journal of Dermatology and Syphilis* and he contributed many papers to the medical press.

When he retired from the active staff of the London Hospital in 1927 Dr Sequeira went out to Kenya but continued to take an interest in medical work of all kinds and particularly in leprosy. He was president of the Kenya Branch of the British Medical Association in 1930-1 and again in 1933-4. He was also editor for over ten years of the *East African Medical Journal*. When war broke out in 1939 his services were again in demand. In the 1914-18 war he had acted as consultant in dermatology to the military hospitals in London. During the recent war he served in the same capacity hospitals in East Africa. Dr Sequeira was one of the most active members of the late Lord Trevellyn's Committee on Venereal Disease, and was at one time chairman of the executive committee of the Society for the Prevention of Venereal Disease. He was also president of the Section of Dermatology of the Royal Society of Medicine in 1925-7, and a corresponding member of the French and Danish dermatological societies.

Dr W J O'Donovan writes. Between the two wars a frequent sight in the London Hospital was the short, very sturdy, white-haired figure of Dr Sequeira walking gravely from bed to bed or across the gardens to the out-patients. Throughout his professional career Dr Sequeira was distinguished by the qualities of gravity and leadership and his clinical acumen was outstanding. From Johannesburg to Toronto, in Leeds, Charing Cross, the Royal Free, and in the London Hospitals his teaching is a tradition carried on by his own professional sons. Before taking up dermatology—and he was the first dermatologist appointed as such to the London Hospital—he was fully trained in both medicine and surgery and was almost unique in holding later the fellowship of both the ancient Colleges. His textbook was an early classic of modern dermatology and when it appeared was unusually lavish in well chosen illustrations.

Dr Sequeira was a master of the treatment of lupus and a pioneer in this country in the clearance of the school population from tinea capitis by an organized mass rav attack upon infected heads in East London. These were the cases ascertained and sent for treatment by the London School Medical Service in its earliest days. He was a pioneer in light therapy, in x-ray therapy and in the use of radium for skin diseases and dermatologists trained by him in this technique have maintained his special interest and competence in radiotherapy. Dr Sequeira served his generation as secretary of the learned

societies and presided with great urbanity and decorum when presidential chairs fell to his lot. He maintained the friendliest of relations with French and Danish colleagues and was frequently visited at his clinic by American dermatologists. His patience in teaching generation after generation of undergraduates was his outstanding virtue. His regularity in hospital attendance was a model of conscientious attention to his voluntary duties. So valued was his teaching that it was common for budding specialists to attend his out-patients clinic twice a week for two years to gain his cachet and to absorb some of his experience and diagnostic methods. His judgment of others was always kindly, and he was ceaseless in encouraging the youngest of his juniors to make original observations and to try whilst they had the opportunities of hospital life to add to knowledge.

At a time when the London Hospital staff included men of outstanding metropolitan distinction Dr Sequeira fully held his own and his memory is revered by hundreds of practitioners and in countless of homes for his benignly judicial and kind personality made a lasting impression on all who met him. Coronary disease attacked him in his eighties and to his wife and his two adopted children we offer our deepest sympathy.

Dr John T Ingram writes. The portly figure and gentle courtly manners of Dr Sequeira reflected his quiet pride in his ancestry. He was the sixth, in direct descent, of a line of doctors and he wore on his little finger the 'morning ring' of one of his doctor ancestors born in the year of the Great Fire of London. When Napoleon invaded Portugal a great grandfather of Sequeira came to London in the train of the Prince Regent of Portugal and was physician to the Portuguese Embassy to the Court of St James's. Sequeira was born and educated in London and was immensely proud of his association with the London Hospital. He had wished to be a physician, being particularly interested in cardiology, but circumstances fortunately determined his being asked to establish a department of dermatology. In his training he had attended lectures by Sir Jonathan Hutchinson and had clerked for Hughlings Jackson. He had little money but he achieved a remarkable postgraduate education. He held resident appointments under Stephen Mackenzie, Warren Tay, and Herman, and was for four years demonstrator in anatomy under Arthur Keith and Wood Jones. He followed this with two years as medical registrar and two years as medical tutor, an apprenticeship of eight years' teaching appointments. He was proud of his associations with Leonard Hill and Lindemann (later Lord Cherwell) and recalled with pleasure tea-parties with William Bulloch and Paul Filder in the bacteriological department.

Two great milestones in medical history influenced Sequeira's work—the physiotherapeutic advances of Finsen and the researches of Ehrlich. He spoke with affection of the interest and encouragement of Sidney Holland (Lord Knutsford) at the London Hospital, and he soon attracted disciples from all over the world and especially from the Dominions and Colonies. He was meticulous in his attention to hospital duties, and kind and generous and helpful to all who worked with him. He would have liked a full-time post at the London Hospital, for he disliked the monetary side of medical practice, but the offer came too late. He was however, strongly opposed to a whole time medical service for the nation. Sequeira greatly admired Radcliffe Crocker's textbook, but his own work was the first to leave the morphological approach to skin diseases and attempt an aetiological classification. He was fond of music, and though he remained a busy man to the end, alert and interested in even new dermatological work, he greatly appreciated the opportunities for indulging his interest in music which came with retirement. He said that he owed everything to two women—his mother and his wife. The devoted affection of his wife undoubtedly enabled him to contribute from his wisdom the work he loved into a ripe old age.

### E LEWIS LILLEY MB, FRCS

Dr Ernest Lewis Lilley who was 72 died quite suddenly in his consulting room on Nov 22 from coronary occlusion. He was a member of an old Leicester family and was educated at the Wiggeston School Leicester. He obtained an entrance scholarship at Channing Cross Hospital and qualified in 1887 graduating MB BS in 1901 and taking the FRCS in

years later He was successively house-surgeon, "house-physician, and R.M.O. at Charing Cross Hospital

In 1904 Dr Lilley came to Leicester, taking over the practice of Dr C Nuttall In his early years he took a great interest in x-ray work, and this stood him in good stead during the first world war He was in charge of the Leicester and Leicestershire Maternity Hospital at its opening in 1904, and he remained in control till it was taken over by the Leicester Royal Infirmary in 1940 In addition to the ordinary routine work of the hospital, including many difficult cases, he trained and lectured to succeeding generations of maternity nurses and midwives Dr Lilley was a member of the board of management of the Leicester Public Medical Service, later becoming chairman, and finally president in 1938, which post he held until his sudden death He was a member and later vice-chairman of the Local Medical and Panel Committee from 1911 He was also a member of the Local Insurance Committee under the N.H.I. He joined the Leicester Medical Society when he started practice, and was elected president in 1928-9

During the first world war Dr Lilley was surgeon to the Fifth Northern General Hospital, Leicester, and later went to Egypt, where he was radiologist to the Citadel Military Hospital, Cairo At the end of the war he returned to Leicester and continued his work until his retirement from general practice in 1939 He was then appointed chairman of the Leicester Recruiting Medical Board He also continued to act as anaesthetist to the Leicester School Clinic and actually gave several anaesthetics on the morning of his death Dr Lilley was an examining factory surgeon and medical referee under the Workmen's Compensation Act and National Insurance Act He was always a keen supporter of the British Medical Association, and was a member of the Council from 1931-43 and of the Insurance Acts Committee from 1921-46 He was chairman of the Leicester and Rutland Division in 1927-8 and he was a member of the Journal Committee from 1921-32 He also served on the Therapeutic Substances and National War Formulary Commission of the Ministry of Health, and became its chairman He was a member of the council of the Medical Defence Union

Dr Lilley, as a member of the council of Leicester University College, was largely responsible for the foundation of the music department there, especially the music library, to which he constantly added fresh books He was on the council of the Leicester Literary and Philosophical Society and became president in 1932 Only a fortnight before his death he read a paper on "Inductive Reasoning" to the philosophical section Apart from medicine his greatest interest was music He was president of the Leicester Chamber of Music and a member of the Philharmonic Society He had been choirmaster and organist at the Great Meeting Unitarian Chapel, Bond Street, Leicester, for about forty years Dr Lilley was an outstanding personality with unbounded energy He was always ready and anxious to do his best for anyone in difficulties He was generous both with his time and money, and went out of his way to help others His advice was often invaluable and always based on a considered and sound judgment  
—E W H

Dr C L Somerville writes With the death of E Lewis Lilley the medical profession in Leicester has lost the most outstanding personality among the older generation of doctors Endowed with an iron constitution and tremendous energy, his capacity for work was a source of amazement to lesser mortals Unfailingly cheerful his chuckling laugh punctuated his conversation His mental calibre matched his energy and together with an acutely retentive memory made him master of a great diversity of subjects from pure science to higher mathematics Fifty years after his days as a demonstrator of anatomy he still had a clear grasp of abstruse details which few practising surgeons of to-day could approach, let alone equal As was to be expected from a man of such attainments his pursuits and hobbies were intellectual, and of these music held first place Outdoor sport had no attractions for him, and I doubt if he ever went for a country walk The live theatre and cinema saw him but seldom, but he rarely missed the concert hall or chamber music recital or the Three Choirs Festival and he knew the organ lofts of churches and cathedrals up and down this country and abroad

In medical matters Dr Lilley's opinion was sound, but in later years he tended to be rather conservative His wide medical knowledge and vast experience were everywhere recognized, and his simple and likable traits endeared him to an immense number of patients and friends He was probably at his heyday about the time of the B.M.A. Annual Meeting in Australia in 1935, and many colleagues will remember him on the tour across Canada and the USA Though he retired from general practice in September, 1939, he kept on several appointments, and throughout the war years he undertook long days of exacting work as chairman of recruiting boards

#### F H S CURD, Ph.D., B.Sc.

Francis Henry Swinden Curd, who died on Dec 2 in Stockport Infirmary at the early age of 39 as a result of a railway accident, was not a member of the medical profession but a chemist on the research staff of Imperial Chemical Industries His death is a serious loss to chemical research and to chemotherapy in this country, for since 1933 he had been engaged on the production of new chemicals, and during the war he was the leader of the team which synthesized the antimalarial drug proguanil or, as it was formerly called, paludrine This compound is the least toxic of the known antimalarials, and, though its potentialities are not as great as was at first hoped, its chemical structure represents an entirely new departure in drugs with an action in malaria Its synthesis was developed by logical steps from mepacrine, the pyrimidine nucleus being first substituted for the acridine ring, later the pyrimidine structure was replaced by a guanidine, leading finally to the formation of N<sub>1</sub>-p-chlorophenyl-N<sub>3</sub>-isopropyl-biguanidine These investigations Curd and his colleagues reported at length in a series of important communications to the *Journal of the Chemical Society* and in the *Annals of Tropical Medicine and Parasitology* In 1947, with D G Davey and F L Rose, he was awarded the Gold Medal for Therapeutics of the Worshipful Society of Apothecaries Before joining the staff of I.C.I., Curd worked for a time in the laboratories of the School of Hygiene and Tropical Medicine, and it was here that his interest was originally aroused in the chemotherapeutic control of tropical diseases

Dr John Kerr writes There was no greater personality in the County Palatine of Chester than Dr Lionel James Picton, of Holmes Chapel Physically a man of rotund build, he had the stoop of the scholar, a kindly countenance with eyes which looked straight at you, and a mental and physical alertness which belied his years The statement in your excellent obituary (Nov 27, p 960), 'though he never published a book,' is incorrect, for his book *Thoughts on Feeding* was published by Faber and Faber in 1946 As secretary of the Local Medical and Panel Committee he instituted an investigation by the committee into maternal morbidity in the county of Cheshire Consequent upon this investigation and the written evidence of Sir Robert McCarrison relative to the important part nutrition played in maternal fitness, the Local Medical and Panel Committee decided to proclaim to the people of Cheshire that the main factor in maintaining health was sound nutrition Dr Picton's natural genius produced the 'Medical Testament' in which he reviewed their experience of twenty-eight years of medical benefit under the National Health Insurance Act He proved that the Act had failed in one of its main objects—the prevention of sickness Dr Picton was an agriculturist of repute and contributed much valuable work on the rearing of livestock Picton was an advocate of raw milk, and maintained that the great nutritional need of the community was an ample supply of clean, fresh raw milk, which could be obtained by the hygienic handling of milk from the healthy cow to the consumer Picton was also deeply interested in soil fertility He contended that, in so far as human health is dependent upon the quality of the food which the body requires, so is the food, whether animal or vegetable, dependent on the soil which sustains it He has shown that the method of composting and returning the whole of the animal and vegetable refuse produced in the activities of a community to the soil results in the health and productivity of crops and of the animals and men who feed thereon To this end he organized on behalf of the Panel Committee, a county garden competition for cottage gardens and allotments to inculcate the much greater use of vegetables in the food of the people Dr Picton's gift of lucid and interesting exposition as a writer enabled him to undertake on behalf

of the Panel Committee the editorship of the *Compost News Letter*. This quarterly was the outcome of much correspondence from all over the world consequent upon the publication of the 'Medical Testament'. It is by men such as Lionel J. Picton, with their scholarship and broad culture, that village life in England is made so delightful. The village of Holmes Chapel, in Cheshire with its fourteenth century church, its inn, and its ancient traditions, has indeed been fortunate. Dr Picton leaves a widow who all through her married life devoted herself to his care. She bore him three sons and three daughters, and two of the sons are now following the profession of their father, one of them carrying on the practice in Holmes Chapel.

Dr SAMUEL ROBERT HUNTER, who died on July 9, was born in Belfast on March 3, 1877, and was educated at the Royal Belfast Academical Institution and Queen's College, Belfast. He took his B.A. degree in the Royal University of Ireland in 1899 with honours in chemistry and physiology, graduated M.B., B.Ch. in 1902, and proceeded M.D. in 1905. He was resident house-surgeon and extern surgeon in the Royal Victoria Hospital, Belfast, before settling down in private practice at Dunmurry. Here, by his genial personality and charming manner, Dr Hunter quickly built up a large practice which extended far beyond the boundaries of his immediate district. He took a great interest in local medical affairs, was a life-long member of the B.M.A., and a fellow and president of the Ulster Medical Society. He volunteered for service with the R.A.M.C. in the first world war, and served most of the time in Salonika and the Middle East. On demobilization Dr Hunter returned to Dunmurry and espoused the cause of the ex-Serviceman. He was president of the Dunmurry Branch of the British Legion from its inception until his death. His leisure was mainly devoted to golf, and he was a past captain of the Dunmurry Club. Dr Hunter's health finally broke down under the stress of work, and in 1945 he retired from active practice and spent his days overlooking his beloved golf-links. He leaves a widow, two sons (Dr G. A. C. Hunter and Lt.-Comdr. Hunter, R.N.), and one daughter.—J. G. J.

Dr LOUISA HAMILTON, who died on Nov. 24, went to the London School of Medicine for Women in 1893, and during her first year began the course for the L.S.A., as the Royal Colleges were not open to women. In 1900 she obtained the M.B. B.S. degree of London University with honours in medicine and obstetrics and in 1906 she proceeded M.D. For a few months after qualification she attended the out-patient and in-patient clinics at Great Ormond Street Hospital for Sick Children. She became a house surgeon at the Elizabeth Garrett Anderson Hospital in 1901, house-physician there in 1902, and house-physician at the Royal Free Hospital a year later. In 1903 she was appointed demonstrator in anatomy at the London School of Medicine for Women. She started private work in 1905 at first in general practice. She worked for seven years in Brunswick Place and in 1912 moved to Nottingham Place, where she was well known for twenty-one years as a physician. She held the post of part-time pathologist at the Elizabeth Garrett Anderson Hospital and later was appointed a member of the staff of that hospital, first as assistant physician, then physician, and finally as senior physician. This post she held till 1936, when she retired. In addition, for many years Dr Hamilton was medical officer to the North London Collegiate School for Girls, the C.E.Z.M.S., and the Methodist Missionary Society. When she retired she went for a trip to Jamaica in 1937 and on the return journey contracted the illness which ultimately proved fatal. Dr Hamilton had many friends and interests. She had the Scottish tenacity of purpose that is satisfied only with the best. This was shown in her medical work but also in the gradual development of her lovely garden in Buckinghamshire. She was an excellent hostess and excelled at cooking. Many generations of students and house-physicians will remember her generous hospitality. Writing as colleague, friend, and patient I can speak from personal knowledge of Dr Hamilton's loyal and sane help. She took a wide view of her patients' needs, and infused into them some of her own courage and common sense. She knew that a great deal goes to the remedy of the ills that we meet, and by her wisdom and sanity she helped many people in many different places, and they all have cause to remember her with gratitude. Louisa Hamilton played a losing game for years with heroic courage. Her loyalty, helpful common sense, and generosity will be remembered.—E. B.

A memorial service for the late Dr Louisa Hamilton will be held at St. Pancras Church, Upper Woburn Place, London, W.C., to-day (Saturday, Dec. 11) at 11.30 a.m.

## Medico-Legal

### TOO SHORT A GESTATION PERIOD

The period of 349 days was recently accepted as a possible gestation period by the Court of Appeal.<sup>1</sup> Subsequently, Mr. Justice Ormerod, in a case heard in the Divorce Court on Nov. 17, accepted expert medical evidence that it was impossible for a normal child to be born after 340 days.<sup>2</sup> On Nov. 26 Mr. Justice Vaisey had to consider what appeared to be a short period of gestation. This was a case under the Guardianship of Infants Acts 1886 and 1926 in which he allowed an appeal from an order of a Metropolitan magistrate making an order for payment by a husband of maintenance for a child. Mr. Justice Vaisey allowed the appeal<sup>3</sup> on the ground that on the evidence from an Army records office, and from hospital case-sheets, the husband against whom the maintenance order was made could not have been the father of the child. He returned from two years' service overseas on Jan. 29, 1945, and had intercourse with his wife on Jan. 31. The wife was delivered of a child on Aug. 8, 1945, an alleged period of gestation of 188 days. Evidence was given that the child was perfectly normal. His Lordship was therefore driven to the conclusion that the child could not have been the offspring of the husband, and the order for maintenance was therefore discharged.

### BERYLLIUM AS A CAUSE OF DEATH

What is said to have been the first fatal case of beryllium poisoning in Great Britain was recently the subject of an inquiry by the East London coroner, Mr. W. R. Heddy.<sup>4</sup> A physicist aged 36, employed by a firm at Edmonton, had been working with beryllium oxide from December, 1941, to December, 1942. He was engaged in work on the development of fluorescent lighting. He remained apparently well until 1945. He then complained of a cough and loss of weight and was eventually admitted to the London Hospital, where he died on Nov. 4. Necropsy showed that death was due to beryllium poisoning.

Beryllium, which was discovered in 1797, was very little known before 1916 and has been of prime economic importance only since 1940. The toxic hazards of beryllium were discussed in an annotation in this *Journal*<sup>5</sup> and subsequently in a leading article<sup>6</sup> an account was given of cases of beryllium poisoning reported from America. At that time among 170 cases of poisoning the chief manifestations were dermatitis, chronic skin ulcer, and inflammatory changes in the respiratory tract, producing in extreme cases a diffuse pneumonitis. A chemical pneumonitis developed in 38 of these workers, of whom 5 died.

## Medical Notes in Parliament

### National Service

The National Service (Amendment) Bill, which was read a first time without debate in the House of Commons on Nov. 24, proposes to increase the period of whole-time service of men called up under the National Service Act, 1948, from twelve months to eighteen months but to reduce their total period of whole time and subsequent part time service in an auxiliary force from seven years to five and a half years. It is further proposed that registered medical practitioners and persons registered in the *Dentists' Register* under the Dentists' Acts, 1878-1923 shall be liable to be called up under the National Service Act up to the age of 30 instead of only up to the age of 26, which applies generally.

### Inadequate Remuneration

Mr. BEVAN told Sir ERNEST GRAHAM-LITTLE on Dec. 1 that he was not aware of severe hardships suffered by doctors as a

## CHRONIC URINARY TRACT INFECTIONS

In infections which fail to respond to treatment, and in which the underlying disease cannot be eradicated, small doses of one tablet of Cystopurin, two or three times daily may be used to control the infection and prevent febrile relapse without producing toxic effects.

The urinary disorders associated with enlarged prostate, stricture of the urethra, acute vesical catarrh, paralysis of the bladder, tuberculosis of the bladder and gonorrhoea may be successfully treated with Cystopurin.

consequence of inadequate remuneration under the National Health Service. He added that this remuneration was based on the recommendations of the Spens Committee and had been agreed upon with the profession. The initial distribution of the total amount of money made available was giving rise to temporary difficulties. These he was discussing with representatives of the profession.

Sir ERNEST GRAHAM-LITTLE also asked Mr Bevan if he knew that his directive to executive councils to the effect that it was not his intention that payments from the Inducement Fund should be made in cases where difficulty could be met by a fixed annual payment would in fact result in a general lowering of the capitation grant, and whether he would withdraw this directive and allow such payments to be met from the Inducement Fund.

Mr BEVAN replied that he saw no reason to alter these arrangements.

### Amending Bill

Mr BEVAN replying on Dec 2 to Sir HENRY MORRIS-JONES said the matter of an amending Bill to the National Health Service Act had been under discussion with representatives of the medical profession. When full agreement had been reached—or when full agreement had not been reached—a Bill would be presented to the House. Sir Henry asked whether the amending Bill would deal with anomalies in the Act which had been clearly demonstrated. Mr BEVAN said Sir Henry had better wait the Bill.

Sir SOMERVILLE HASTINGS asked if Mr Bevan knew of the many expressions of satisfaction received from all sections of the community.

Mr BEVAN said that undoubtedly many millions of people had already benefited under the Act. He hoped that when the report of the Ministry of Health came to be presented to Parliament it would give an objective review of what had happened.

Sir HENRY MORRIS-JONES gave notice that he would raise his matter on an adjournment of the House.

*The Doctor's Bag*—Sir WALDRON SMITHERS on Nov 30 asked the Chancellor of the Exchequer, in view of the extra pressure of work placed on doctors under the new Health Act, to exempt from purchase tax articles necessary for the use of doctors in their professional duties especially the doctor's bag. Sir STAFFORD CRIPPS refused to do this. He said it was not possible to give doctors special privileges for the few chargeable articles they used professionally.

*Certificates for Spectacles*—Dr SANTO JEGGER on Dec 2 asked the Minister of Health whether, in view of the pressure of work on doctors the long waiting in doctor's waiting rooms, and the formal nature of the certificates involved, he would remove the necessity for patients requiring to have their eyes tested by opticians to obtain doctors' certificates saying so. Mr BEVAN replied that this requirement was instituted in the light of advice received from the medical profession. He would not feel justified in abolishing it except on professional advice.

## The Services

Surgeon Lieutenant Commanders R E King, W I D Scott, and T Gaunt, R.N.V.R., have been awarded the R.N.V.R. Decoration.

The President of the USA has conferred the Bronze Star Medal on Lieutenant Colonel (Temporary) E Samuel, Major (Temporary) Noble, M.C., and Captain (Temporary) R W Preston, R.A.M.C., in recognition of distinguished services in the cause of the Allies.

The King of the Hellenes has conferred the following decorations in recognition of distinguished services in the cause of the Allies:

*Grand Cross of the Royal Order of the Phoenix*—Major-General C A Dawse, C.B., C.B.E., M.C., late R.A.M.C.  
*Commander of the Royal Order of the Phoenix*—Captain A M and R.A.M.C.

The Prince Regent of Belgium has conferred the following decorations in recognition of distinguished services in the cause of the Allies:

*Officer of the Order of Leopold*—Colonel (Temporary) J P J and R.A.M.C.

*Croix Militaire 1st Class*—Major F H Newland, Major (Temporary) E James, and Captain S Howe, R.A.M.C.  
*Croix Militaire 2nd Class*—Major (Temporary) W Barnes, R.A.M.C.

## DEATHS IN THE SERVICES

Sir Matthew Fell, K.C.B., C.M.G., writes: My old friend, Lieut-Col J C JAMESON, R.A.M.C., died last July after a long illness patiently and philosophically borne. He was the eldest son of the late Surgeon General J Jameson, C.B., K.H.S., who was Director-General of the Army Medical Service at the outbreak of the South African war, and was a graduate of Edinburgh University. I met him first at the Orange River Bridge in November, 1899, when Lord Methuen's Force was concentrating for the advance on Kimberley, and after that he continued under the same commander until 1902, wandering throughout the West of the Orange Free State and Western Transvaal. Jameson had previously served in the Afrikaner Campaign on the North West frontier of India, and was later to serve with me throughout the first world war. But it was the close daily contact of three years on the veldt that formed our friendship, which lasted without a break to the time of his death. He was a keen golfer and also a fisherman, and after his retirement we had many happy days together. He never married, but children and young people loved him. Having the limelight, self-effacing, careless of his appearance, almost hyper-conscientious in his professional work, anxious to give of his best at work or play, he was a truly lovable character, and the world is the poorer for his passing.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

In a Congregation held on Nov 27 the degree of M.A. was conferred on James Wilson Millen, M.D., University Demonstrator in Anatomy. The degree of M.D. was conferred on T St M Norris (by proxy) and D S Short.

### UNIVERSITY OF DURHAM

Sir Henry Dale, O.M., F.R.S., will give the fourth Rutherford Monson Lecture in the Royal Victoria Infirmary, Newcastle-upon-Tyne, on Thursday, Jan 20, at 5 p.m. His subject is 'Physiology and Surgery'.

### UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

POSTGRADUATE DIPLOMA IN PSYCHOLOGICAL MEDICINE—*With Mental Diseases (Psychiatry)* in Part B: I R C Batchelor, D D Howell, D W Liddell, D L Murti, Rao A, J P Oldham, J W T Redfern, Ethel E Robertson, I T Robinson, D Stafford Clark, A C Tant, R W Tibbitts. Dr Thomas D Dublin has been appointed executive director of the American National Health Council. For the last six years he has been professor of preventive medicine at the Long Island College of Medicine, Brooklyn. The National Health Council was founded in 1921 by a group of national health organizations. It has recently received a grant of \$225,000 from the Rockefeller Foundation.

## Medical News

## Advisory Committee on Medical Nomenclature and Statistics

The Registrar General has set up an Advisory Committee on Medical Nomenclature and Statistics. The function of the committee will be to consider from the medical point of view and to advise upon questions affecting the international statistical classification of diseases, injuries, and causes of death and many other matters concerning medical nomenclature or statistics which may from time to time be referred to it. The chairman is Sir Ernest Rock Carling and the members are Sir Allen Daley, Professor Ernest Finch Dr F H K Green, Dr C F Harris, Professor A Bradford Hill, Professor A J Lewis, Dr A Massey, Dr P L McKinlay, Professor N C W Nixon, Dr W N Pickles, Dr A H T Robb-Smith, Dr Percy Stocks, Professor R E Tunbridge, Sir Lionel Whitby, and Dr A Louise Winner. The secretary of the committee is Mr L M Feery, General Register Office, Somerset House London, WC2

## Industrial Health Research Board

The following have accepted the invitation of the Medical Research Council to serve as members of the Industrial Health Research Board during the next three years. Sir Frederic C Bartlett, FRS (chairman), Sir Charles J Bartlett, Professor R V Christie, FRCP, Mr C R Dale, Dr A N Drury, FRS, Sir Luke Fawcett, Professor T Ferguson, MD, Sir Claude Gibb, FRS, Professor A Bradford Hill, Professor Esther M Killick, MRCP, Professor R E Lane, FRCP, Dr A Massey, Dr E R A Merewether, Dr J M Rogan, Dr Donald Stewart, and Dr Joan M Faulkner (secretary). The Board is appointed by the Council to advise and assist it in that part of its research programme which relates to occupational health. The detailed consideration of research work is in the hands of scientific committees dealing with such subjects as occupational medicine, occupational physiology, occupational psychology, industrial pulmonary diseases, toxicology, and statistics. These committees report directly to the Council for purposes of immediate action. The function of the Board itself is that of a reviewing body considering general policy with regard to research over the whole field.

## The Royal Society

At a meeting of the Royal Society, held on Nov 30, the following officers were elected for the ensuing year. President Sir Robert Robinson, Treasurer Sir Thomas Merton Secretaries Sir Edward Salisbury and Professor D Brunt Foreign Secretary Professor E D Adrian, OM, MD. Fifteen other Fellows were elected to the Council of the Society, including the following members of the medical profession. Professor G R Cameron, FRCP, Dr C H Kellaway, FRCP, and Professor S Zuckerman, MD.

## Higher Pay for Hospital Domestic

Agreement has been reached by the Ancillary Staffs Council of the Whitley Council for the Health Services (Great Britain) on revised rates of pay for domestic and manual workers in hospitals and institutions. They will also apply to residential establishments controlled by local authorities. The revised rates for the basic grades are 106s for men and 82s for women in London, 100s for men and 75s for women in urban areas, and 97s for men and 74s for women in rural areas. These new rates will in general result in increases ranging from 1s to 8s a week for men and from 2s to 7s a week for women, and are based on a 48 hour week. About 130,000 employees are affected.

## Advisory Council on Child Care

The Home Secretary has appointed the Advisory Council on Child Care provided for in the Children Act. The members are Professor Alan Moncreff (chairman), Lady Allen of Hurtwood Dr Muriel Barton Hall, Mr R Beloe, Miss S C Bertie, Mrs F M Brown, Mr P B Dingle, Mrs K W Jones Roberts, Mr P T Kirkpatrick Mrs Dermot Morrish, Miss L M Rendel, and Mr David Smith. Departmental representatives of the Home Office and the Ministries of Education, Health, and Labour have also been appointed.

## One Man's Story

'One Man's Story' is a film which has been produced for the Foreign Office by the Central Office of Information with the object of telling people, in this country and overseas about British achievements in public health. It is a description of the work of the late Dr G C M McGonigle who was medical officer of health for Stockton-on-Tees from 1925 until his death in 1939, and it illustrates the manifold duties which medical officers of health are called upon to perform. The film in particular brings out McGonigle's observation that in spite of the transfer of half the residents of a slum area in Stockton to a model housing estate their health did not show the

expected improvement, and at the end of five years the death rate was rising in spite of better housing. The simple reason was that the people, having to spend rather more on rent, spent rather less on food and the lesson was drawn home that social improvement was not to be brought about by attention to only one factor in the situation. The part of M Gonigle in the film is taken by Murray Mathe son, but apart from one other there are no professional actors in the film, the cast consisting of members of the council and citizens of Stockton, where nearly all the filming was done. Perhaps the desire not to make too long a film—it runs for only 26 minutes—has resulted in some aspects of M Gonigle's work being passed over lightly. But it is a very human presentation. It brings out the two sides of a medical officer of health's work—the control of hygiene and the personal services. It is produced by the Horizon Film Unit in association with the Film Producers Guild, and Dr M Gonigle's successor at Stockton-on-Tees, Dr H J Peters, has co-operated.

#### World Federation for Mental Health

The report of the International Preparatory Commission of the Congress on Mental Health, which met in London in August, has been issued under the title "Mental Health and World Citizenship." It is obtainable for 1s (1s 2d post free) from the World Federation for Mental Health, 19, Manchester Street, London, W 1.

#### Literature of Food Investigation

The Department of Scientific and Industrial Research has issued the *Index to the Literature of Food Investigation*, Vol 17, No 1, June, 1945 (HMSO 6d). Short notes on the contents of each article follow the reference to it.

#### Wills

Mr Robert Ollerenshaw, of Didsbury, Manchester, left £104,071. Dr Robert Haslam of Bolton, left £24,823. Dr Charles Albert Ernest Griffiths, of Meopham, Kent, £5,281. Dr Charles Dainty Hatrick, of Hadley Wood Middlesex, £5,081, and Surgeon Rear-Admiral James Herbert Fergusson, late R.N., £1,483.

### COMING EVENTS

#### Congress of Comparative Pathology

Titles of papers to be presented at the Fifth International Congress of Comparative Pathology (Nov 20 p 923) at Istanbul should be sent by Dec 15 to Mr R E Glover, Royal Veterinary College, London, NW 1. The papers should be sent by Feb 20 1949, to Pr N R Belger, Taksim, Siraserviler 75/3, Istanbul, Turkey.

### SOCIETIES AND LECTURES

#### Monday

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W—Dec 13, 8.30 p.m. *Therapeutic Application of Anticoagulants*. Discussion to be introduced by Dr Paul H Wood and Mr A Dickson Wright.

#### Tuesday

CHADWICK TRUST—At Royal Society of Tropical Medicine and Hygiene 26 Portland Place, London, W, Dec 14, 2.30 p.m. *The Rise and Fall of the First General Board of Health* by Mr S E Finer.

CHelsea CLINICAL SOCIETY—At South Kensington Hotel 47, Queens Gate Terrace London SW, Dec 14, 7 for 7.30 p.m. Discussion *Films and their Influence*. To be opened by Mr Sidney Gilliat (J Arthur Rank organization).

INSTITUTE OF DERMATOLOGY, 5, Lisle Street Leicester Square London WC—Dec 14 5 p.m. *Histopathology of the Skin* by Dr I Muende.

INSTITUTE OF UROLOGY—At St Paul's Hospital Endell Street, London WC Dec 14 11 a.m., *Cerebrospinal Fluid Tests for Syphilis* by Dr R Thomson at St Peter's Hospital Henrietta Street London WC Dec 14, 5 p.m. *Congenital Defects of the Testicle and Epididymis* by Mr Harland Rees.

PINOTHIOTHERAPISTS ASSOCIATION OF GREAT BRITAIN—At Charing Cross Hotel Strand London WC, Dec 14 8 p.m. *Physical Medicine in Diseases of the Endocrine Glands* by Dr A P Canadinas.

SOCIETY OF CHEMICAL INDUSTRY FOOD GROUP LONDON SECTION, AND AGRICULTURE GROUP—At Main Chemistry Lecture Theatre, Royal College of Science Imperial Institute Road London SW, Dec 15 5.30 p.m. Joint meeting. Address *World Cereals To-day* by Mr C A Loombe.

#### Wednesday

INSTITUTE OF DERMATOLOGY 5, Lisle Street Leicester Square, London WC—Dec 15 5 p.m. *X-ray Technique* by Dr, C W McKenna.

INSTITUTE OF UROLOGY—At St Paul's Hospital Endell Street London WC, Dec 15 11 a.m. *The Toxic Manifestations of Treatment in Syphilis* by Dr W N Mascall, 5 p.m. *Tumours of the Testicle* by Mr W K Irwin.

#### Thursday

EDINBURGH CLINICAL CLUB—At BMA Scottish House, 7 Dr Hugh Gardens, Edinburgh, Dec 16 8 p.m. *The Therapeutic Use of the Minerals* by Dr A G Badenoch.

INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street London, WC, Dec 16 11 a.m., *The Toxic Manifestations of Treatment in Syphilis* by Dr W N Mascall at St Peter's Hospital, Henrietta Street, London, WC, Dec 16, 5 p.m., *Injuries and Disease of the Testicle and Epididymis other than Tumour or Tuberculosis* by Mr Harland Rees.

ST GEORGE'S HOSPITAL MEDICAL SCHOOL Hyde Park Corner, London SW—Dec 16, 4.30 p.m. *Neurology and Psychiatry*. Lecture demonstration by Dr Anthony Feilung.

#### Friday

LONDON CHEST HOSPITAL, Victoria Park, E—Dec 17, 5 p.m. *Clinical and Cardiographic Methods in the Diagnosis of Coronary Syndromes* by Dr K Shirley Smith.

MAIDA VALE HOSPITAL MEDICAL SCHOOL, Maida Vale London, W—Dec 17, 5 p.m. Case demonstration by Dr E A Blake Pritchard.

### APPOINTMENTS

BRINDLE T W, M.B. Ch.B. Full time Medical Officer for Central Area of Flintshire.

GEE A C MRCS LRCP DPH Medical Officer of Health Lowestoft.

GRETTON WATSON B G MB BChir DPH Deputy Medical Officer of Health for Cheshire.

RHYDWEN R DSC MB, BS, DPH, Full time Medical Officer for Western Area of Flintshire.

THOMPSON B A MRCS LRCP Assistant Pathologist Watford Peace Memorial Hospital North West Metropolitan Regional Hospital Board.

THORBURN A L MD DPH Divisional School Medical Officer and District Medical Officer of Health for the Urban and Rural Councils of Nantwich Cheshire.

### BIRTHS, MARRIAGES, AND DEATHS

#### BIRTHS

Child—On Nov 28 1948 at the General Hospital Newcastle upon Tyne to Margaret wife of Dr J P Child a son.

Darcus—On Nov 27 1948 at Churchill Hospital Oxford to Mary wife of Howard Darcus BM a son.

Ebbage—On Nov 29 1948 at Highbury to Margaret (née Cunnison) wife of Geoffrey Ebbage a son—Jan.

Miller—On Nov 24 1948 at Belfast to Noel (née Gardiner) wife of Geoffrey Miller MRCP1 Riversley Banbridge Co Down a daughter.

Smith—On Dec 1 1948 at the Barratt Maternity Home Northampton to Sheila (née Macbrat) wife of Alastair W Smith MBE LRCP & Sed LRFP & Glas a daughter.

Stevenson—On Nov 28 1948 at King's College Hospital London SE to Marjorie (née Ferguson Wood) wife of John Stevenson MRCS LRCP a son.

#### DEATHS

Chambers—On Nov 23 1948 at The Winnats St Helens Isle of Wight Wilfrid Metcalfe Chambers MD aged 66.

Drew—On Nov 27 1948 at White Lodge Fleet Charles Milligan Drew DSO MB ChB retired Colonel AMS aged 68.

D Rosario—Recently Wilfred James D Rosario MRCS LRCP of Carlisle Cumberland.

Ferguson—On Nov 28 1948 at Braeside Bishop Auckland Co Durham Tom Entwistle Ferguson LRCP & Sed LRFP & Glas.

Grove—On Nov 28 1948 William Reginald Grove MD of St Ives Hunts aged 79.

Hamilton—On Nov 24 1948 Louisa Hamilton MD of Aylesbury Bucks.

Lilley—On Nov 22 1948 Ernest Lewis Lilley FRCS of New Walk Leicester aged 72.

Linklater—On Nov 24 1948 at City Hospital Edinburgh George James Irvine Linklater OBE MDEd.

Macrae—Recently at Worcester South Africa Duncan Mackenzie Macrae MD.

Moncreiff—On Dec 1 1948 at 8 Queen's Road Hendon London NW Agnes Moncreiff MB ChB.

Parsons—On Dec 4 1948 at Nuffield House Guy's Hospital London SE Frank Bett Parsons MD FRCP of 77 Grange Road Cambridge aged 46.

Rawlings—On Nov 23 1948 at Cambridge Graham Rigby Rawlings MB BChir late of Calcutta.

Reid—On Nov 29 1948 at Ashleigh Linthorpe Middlesex John Bernard Reid MCh FRCS Ed aged 48.

Rooke—On Nov 26 1948 at Woodhouse Head Newbury Berks Frederick James Faulkland Rooke MRCS LRCP LDS aged 77.

Scott—On Dec 1 1948 at Craig Barns Frensham Vale near Farnham Surrey John Livingstone Scott MB ChB.

Sequeira—Recently in Kenya James Harry Sequeira MD FRCP FRCS aged 83.

Stuart—On Nov 26 1948 at Westwood Oakfield Road Harpenden Herts Emily Gertrude Stuart MB formerly of the C.E.Z.M.S. Hospital Quetta aged 76.

Topham—On Nov 28 1948 at Folkestone John Arthur Topham MRCS LRCP formerly of Chatham aged 74.

Whiteman—On Sept 23 1948 John Wells Whiteman MRCS LRCP aged 68.

## INFECTIOUS DISEASES AND VITAL STATISTICS

The print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov 20

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only

† Deaths from measles and scarlet fever for England and Wales (London (administrative county)) will no longer be published

‡ Includes primary form for England and Wales (administrative county) and Northern Ireland

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales (administrative county) are combined

†† Includes puerperal fever for England and Wales and Eire

## EPIDEMIOLOGICAL NOTES

## Type "J" Typhoid Fever

There is reason to believe that three patients, suffering from typhoid fever one at Plustow, one at Romford, and one at Lyme Regis contracted the infection while en route from Australia to the United Kingdom where they arrived in the first week of November. The organism responsible appears to belong to Vi phage type 'J' which is not indigenous in England and Wales. It can be fairly assumed that type 'J' infections appearing here at the present time come from a common source and it is suggested that practitioners caring for patients suffering from typhoid should make a special effort to see that strains of the infecting organism reach the National Public Health Laboratory Service. M O S H hearing of other patients who may be associated with the incident are asked to send details direct to S M O, Med III, Ministry of Health, Whitehall

## Poliomyelitis in Iceland

An outbreak of infantile paralysis has occurred in Akureyrri, in the North of Iceland. Up to Nov 24 160 cases had been reported, the majority in children. All schools in the town have been closed and public meetings forbidden. Mild outbreaks of 'influenza' and 'gastritis' are also reported from Akureyrri

## Discussion of Table

In England and Wales an increase in the number of notifications was recorded for scarlet fever 385 whooping cough 199, and acute pneumonia 153 and there was a decrease for dysentery 84 and acute poliomyelitis 14

A small rise in the incidence of scarlet fever was reported from every region, the largest local rises were Lancashire 46 and Yorkshire West Riding 45. The largest fluctuations in the local trends of whooping cough were increases in Southampton 39 and Warwickshire 38 and a decrease of 53 in Lancashire. Notifications of measles for the whole country increased by 13, but there were considerable variations in local returns the largest increases were Yorkshire West Riding 103 and Durham 46 and the largest decreases were Derbyshire 130 Suffolk 64 and Lincolnshire 49. Only small changes were recorded in the local incidence of diphtheria. An increase of 37 in the notifications of acute pneumonia in Lancashire was the only change of any size in the local trends

Of the 9 cases of typhoid fever 3 were notified in Liverpool C B. No further cases of dysentery were notified from the outbreak in Essex Hornchurch U D, where 60 cases occurred last week. The largest returns of dysentery were Lancashire 12 and London 10. The largest returns of acute poliomyelitis were London 4, Middlesex 4, Gloucestershire 4, and Yorkshire West Riding 4

In Scotland a rise occurred in the incidence of infectious diseases and increases in the number of notifications were reported for measles 34 acute primary pneumonia 25, and scarlet fever 23. In the city of Aberdeen 6 further cases of paratyphoid fever were notified, this makes a total of 29 cases in the past three weeks. The notifications of diphtheria in the city of Glasgow were 5 more than in the preceding week

In Eire rises occurred in the notifications of measles 19 and whooping cough 12, while decreases were reported for scarlet fever 33 and diarrhoea and enteritis 17. An outbreak of measles affecting 26 persons was notified from Tipperary, Nenagh R D. The decline in diarrhoea and enteritis was due to a fall of 17 in the number of notifications in Dublin C B

In Northern Ireland an increase of 8 was recorded in the notifications of measles from Belfast C B

## Week Ending November 27

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1 544, whooping cough 2 747, diphtheria 141, measles 8 547, acute pneumonia 716, cerebrospinal fever 36, acute poliomyelitis 42, dysentery 72, paratyphoid 1, and typhoid 3

Dr C H Andrewes, F R S, who since 1927 has been a member of the Scientific Staff of the National Institute for Medical Research left Britain recently to lecture in Hungary for the British Council on 'The Common Cold' and 'Recent Work on Influenza'. Dr Andrewes is in charge of the Medical Research Council's scientific investigations into the common cold at Salisbury and was one of the team which first isolated an influenza virus in 1933

## AT THE FIRST GASP

Clinical experience has amply confirmed original reports on the value of 'Neo-Epinine' in the treatment of bronchial asthma. Equal to adrenaline and superior to ephedrine in anti-asthmatic activity, it is relatively free from the undesirable side-effects of both these drugs. 'Neo-Epinine' is administered simply, either sublingually or by oral inhalation, thereby avoiding the necessity for injection. Issued for sublingual administration as compressed products each containing 20 mgm, in bottles of 25 and 100, and as 1 per cent Spray Solution in bottles of 10 c.c.

### 'NEO-EPININE'

ISOPROPYL ADRENALINE SULPHATE

BURROUGHS WILLCOCKE & CO (The Wellcome Foundation Ltd) LONDON

### The **HECSON** SUPER ELASTIC TRUSS for the Treatment of Hernia

Truss is fixed to Pad at A. Therefore greater pressure is exerted at B, when the strap is pulled tightly.

Where treatment of Hernia by surgical methods is undesirable for any reason, the HECSON super elastic truss can be confidently recommended. The Special Feature of the HECSON Truss is that the perineal or under strap is attached to the top of the pad instead of the lower margin as in the ordinary elastic or old spring truss. Thus it becomes part of the leverage mechanism for increasing the pressure of the pad at its base.

Price Single £2 12s 6d  
Double £3 13s 6d

Further particulars on request from the manufacturers

### The CURTIS Service

We regret that owing to shortage of materials and labour, we are frequently prevented from making such prompt deliveries as has been our custom in the past. We do however assure you that every possible effort is being made to maintain our usual high standard of workmanship and prompt delivery.

### Temporarily Lengthened

During pregnancy, uterine muscle fibres may reach ten times their usual length to accommodate the growing foetus. After parturition, 'Ergotrate' administered two or three times daily, will hasten uterine involution by holding the muscle in a state of contraction. Haemorrhage is prevented and a barrier to infection is established.

# 'TRILENE'

## *A safe and valuable anaesthetic*

'Trilene' is now universally accepted as a safe and valuable anaesthetic for most operations. It can be used for induction or maintenance, or for maintenance with curare.\* Notable advantages are the small quantities needed, the rapidity of recovery and the absence of vomiting and other unpleasant after-effects.

'Trilene' has also been used with great success to produce safe and reliable analgesia.

*\* An abstract of a report on these uses in over 40,000 cases is available*

Literature and information will be supplied on request from your nearest ICI office - London, Bristol, Manchester, Glasgow, Edinburgh, Belfast and Birmingham.

## WEATHERING THE FORTIES

The Roaring Forties were a searching test of seaworthiness for the sailing ship. So for men are the Forties—in years of age—a period of stress, revealing any latent defect. It is then that many observe the first symptoms of hypertension.

If business commitments allow no easing of physical and mental strain, symptomatic treatment is indicated. This improves the patient's psychological state and tends to check progress of the condition.

'Theominal' is a preparation combining vasodilator, sedative and antispasmodic properties. Its wide use in hypertension attests its value.

## 'THEOMINAL' IN HYPERTENSION

*'Theominal' is a combination of Lumina and Theobromine*

*Packings of 20 50 250 tablets*

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Lobeline and Asphyxia Neonatorum

**Q**—What is the value of an injection of lobeline in an asphyxiated newborn baby? Is it specific in these circumstances? If not, what percentage of success can be obtained?

**A**—Lobeline hydrochloride given by injection is reputed to stimulate the respiratory centre in the medulla and to increase its sensitivity to carbon dioxide. However, it cannot be regarded as a specific remedy for asphyxia neonatorum, its effect being very inconstant. Many authorities now doubt whether it is of any value at all, and American writers in particular are sceptical. It is argued—and there is some animal experimental work in support—that in severe anoxaemia the respiratory centre is incapable of being stimulated by lobeline, which in such circumstances may even be harmful. In these cases the real need is for oxygen. Even though such an extreme view is not widespread in this country it is generally recognized that the use of lobeline hydrochloride and other stimulants is of secondary importance in the treatment of asphyxia neonatorum. It should be added that traditional views on the action of lobeline hydrochloride are now disputed, and it is suggested that the drug increases respiration by exciting the carotid sinus reflex. Even if it has such an effect, however, it is admitted that this is both transient and variable.

### Anaesthesia for Tonsillectomy

**Q**—What is the best method of anaesthesia for dissection of tonsils in children aged 4 to 8? I have used ethyl chloride but the duration of anaesthesia is limited and not always sufficient.

**A**—A variety of anaesthetic techniques are in use for this operation. The commonest, and one that gives excellent results, is as follows. The child is given an injection of atropine, as well as a sedative consisting of a moderate dose of "seconal" or morphine. Anaesthesia is induced with ethyl chloride on an open mask followed by drop ether. When the jaw is relaxed and the child is well under, the mouth is opened and the particular gag of the surgeon's choice inserted, anaesthesia is maintained by insufflation of ether vapour with air or oxygen into the mouth and pharynx. Dissection of tonsils in children is generally a short operation, and no difficulty will be encountered in keeping the child under by the means described. The shortness of the operation, the ease with which the larynx in a child of this age may be damaged, and the satisfactory anaesthesia obtained by insufflation of the vapour alone normally make the insertion of an endotracheal tube unnecessary, although some experienced anaesthetists do it as a routine.

### Post-traumatic Neurosis

**Q**—Two years ago a man aged 42 hurt his back when lifting a bag of potatoes on to a cart. Three days later he found he could not walk without pain. No x-ray evidence of damage has been found and the patient has been pronounced neurasthenic. Under narcosis he shows no conflict whatever regarding compensation etc. He dreads his left leg after him, refusing to bend, crouch or kneel. What further treatment do you recommend?

**A**—The writer is not wholly satisfied from the description given that the case is necessarily neurotic. The exclusion of organic causes by x-rays is of course important and necessary, but the prevalent habit of diagnosing a case as neurotic simply on the grounds that no organic condition is found should be avoided. The fact that an organic cause cannot be found does not always mean there is not one. No doubt before the discovery of the vitamins many cases of depression due to vitamin deficiency were read as psychogenic because no organic cause could be found. Neuritic and hysterical conditions are to be

diagnosed on positive as well as negative grounds, and the patient's psychological history and his personal problems, conscious and unconscious, at the time of the trauma, as well as the events of the accident, must be investigated. In this case one such positive factor has rightly been taken into consideration—that of compensation. But there may be other reasons for resorting to a hysteric symptom. In the occupational neuroses, for instance, there is a latent desire to escape from work which the patient finds uncongenial but which he is compelled to do either from necessity or from some moral obligation (Telephone-girl's deafness and the "war neuroses" of soldiers are instances of such occupational neuroses). But there are many other problems of an infinitely more complicated nature which may be at the bottom of the neurosis (if this is one).

Repeated suggestion under narcosis may be of service, but it has the weakness of all suggestive treatment—namely, that it may be working against the patient's unconscious wish to be ill, as in the occupational neuroses. It is a case of the physician's suggestion versus the more deeply rooted autosuggestion of the patient. The number of treatments therefore depends on the strength of the unconscious resistance of the patient against cure, as well as on the toxicity of the drugs. Analysis under drugs we should expect to give the better results, since emotional problems often emerge under narcosis, but this is by no means an infallible method, and often draws a blank. In any case, the patient should be left to reveal his own problems even under narcosis. If that fails, analysis under free association by an expert medical psychologist, which is longer but surer than the other methods, should be resorted to, if such treatment can be obtained.

### Syringing Ears

**Q**—Is there any contraindication to the use of soap substitutes in syringing ears for wax?

**A**—There is no contraindication to the use of soap substitutes, but these are not necessary. Plain warm water is quite effective, provided it is directed along the postero-superior meatal wall, when quite a powerful jet will cause no discomfort. Bicarbonate of soda may usefully be added to the water.

### Cysts of the Breast

**Q**—A woman of 44 has had cysts in her right breast for three or four years. They are not adherent to any tissue. Lately they have become somewhat harder on palpation. Could dienoestrol which is being taken for menopausal disorders in any way affect the pathology of the cysts? Would surgery be advisable?

**A**—If the cysts are part of what is known as chronic mastitis, the condition would be aggravated by dienoestrol and ameliorated by testosterone. As some of the nodules are said to become harder on palpation, a surgical opinion on their innocence should be sought. Should malignancy be excluded, it is probable that surgery would not be called for. On the history malignancy seems unlikely.

### Stammering

**Q**—My small son aged 3½ has recently developed a bad stammer. This is getting worse. There appears to be no mental conflict and he is healthy and happy. He is an only child of rather above average intelligence, and he is more right-handed than left-handed. He has not heard anyone else stammer and playing with other children makes no difference. Is this a phase which will pass? If not, what steps can I take to cure the condition before it becomes well established?

**A**—It is difficult to be sure about the cause of the stammer in this case without knowing more of the factors associated with its onset. It might be connected with some change in the child's life such as starting a nursery school or an alteration in the environment. It may also be that his ideas are outrunning his verbal powers, so that he thinks more quickly than he can speak. One may detect the latter condition by noting the kind of stammer, which would probably be of the repetitive type, as if he were "tumbling over his words". If so, it would help him if he were spoken to slowly and in as simple language as possible. He might also learn to use speech more comfortably by associating this with rhythm in rhymes and songs. If his

stammer is of the blocking, explosive type he should see a speech therapist, and should do so in any case if the stammer does not clear up within the next few months

#### Arterial Disease

**Q**—What drugs have any effect on endarteritis or atheroma in a man of 62 with normal blood pressure and electrocardiogram and with a negative Wassermann reaction? He has pain over the carotid and bronchial arteries but negligible angina

**A**—Points which need to be considered are the aetiology, position, and extent of the endarteritis, the location of the atheroma and whether the pain is spontaneous or occurs on pressure or with exercise. Unless endarteritis is due to syphilis or chronic suppurative lesions, we know of no drug that will affect it. Similarly there is no known therapeutic agent for atheroma. The circulation can be improved by coronary vasodilators and undue cardiac strain avoided by limiting exercise to the point of anginal pain or breathlessness.

#### Delousing Heads by "TIFA"

**Q**—I recently read an American article describing the Todd insecticide fog applicator (TIFA). Could you tell me if anything comparable to this machine exists in this country, and if so its approximate cost? I contend that children with pediculosis capitis might be passed through a room containing a suitable proportion of DDT fog applied with the TIFA or the like at regular intervals. Could I have your advice?

**A**—The TIFA fog insecticide disperser has been tested in this country but, so far as we are aware, is not manufactured here. It is a rather wasteful method of dispersing very large quantities of insecticide rapidly and over large areas. It might have advantages in large scale field treatments, where, for example, it is desired to eradicate tsetse flies from large areas of African bush or to destroy rapidly all the mosquitoes in a small town or a large camp site. It is difficult to see why one should employ such a large, elaborate machine for the exceedingly simple procedure of applying insecticide to verminous heads. Several excellent preparations are available such as "Iethane special" (*British Medical Journal* 1942, 1 464) DDT emulsion (*ibid.*, 1945 1, 409), or gamma-BHC (*Med. Officer* March 20, 1948). All of these are better applied by hand than by a fog in the air.

#### Care of the Hair and Scalp

**Q**—(a) What happens to the hair and scalp if left unwashed for a long time say two years? (b) Is water or washing inimical to the health of the hair? (c) What are the most healthy materials for washing hair? (d) What is the best treatment for dandruff?

**A**—(a) Provided brushes and combs are washed frequently, and the hair is well brushed daily a healthy scalp and hair need not be washed for years.

(b) Hard water and alkaline soaps are not good for the hair. With proper care there is no objection to frequent washing. This is not advisable except where the hair is very oily or the scalp has much dandruff.

(c) Rain water soft water, and any good soap are best for the purpose. For the many methods which are harmless consult a book on dermatology.

(d) Dandruff (pityriasis capitis) is too big a problem to answer without examining the patient. If left alone, the next stages—pityriasis steatoides and circinata, with redness, exudation, and crusting—may develop. For simple dandruff use salicylic acid, gr 8 (0.52 g) and/or liquor carbonis detergens,  $\frac{1}{2}$  to 1 drachm (1.8 to 3.5 ml) to the ounce (28.4 ml) of industrial spirit and water equal parts. Some respond better to mercurial preparations. For severe cases the same drugs may be used in ointment form.

#### Penicillin and Tuberculosis

**Q**—Tuberculous abscesses after penicillin injections have been described. Is the incidence of tuberculous infection following penicillin injection higher than after other types of injection? Does penicillin favour the growth of *Mycobacterium tuberculosis*?

**A**—When tuberculous abscesses have resulted from therapeutic injections they have usually been due to the use of a contaminated syringe. The kind of material injected is likely

to be of little consequence if it contains living tubercle bacilli and presumably this occurrence is not so common that the incidence of tuberculous infection after penicillin and other injections can be compared statistically. According to Ungar and Muggleton (*J. Path. Bact.*, 1946, 58 501) penicillin stimulates the growth of *Myco. tuberculosis* in culture. Rivière Thély, and Grutron (*C. R. Acad. Sci. Paris* 1947 224 1856) have reported that penicillin treatment accelerates death from tuberculosis in the guinea pig, and Hruduroy and Rosset (*Ann. Inst. Pasteur* 1948, 75 67) who have repeated these experiments believe such deaths to be caused simply by penicillin itself which is far more toxic to guinea-pigs than to any other animal.

## NOTES AND COMMENTS

**Ulceration of Mucous Membranes**—Dr JAMES M. CANNINO (Mitcham Surrey) writes: With reference to the above subject, on which questions and answers have previously appeared in the *Journal* ('Any Questions?' Aug 21, p 408; March 15, 1947, p 365; June 15, 1946, p 940; Dec 25, 1943, p 839), I should like to advance a suggestion which may in some cases be of assistance to those practitioners who have had the disconcerting experience of endeavouring to alleviate this notorious and frequently quite intractable malady. I have observed within the past two months a definite and very dramatic improvement in three cases of recurrent ulceration of mucous membranes from the exhibition of 'benadryl'. In all three cases, which were female, the ulcers appeared chiefly on the mucous membranes of the mouth, tongue gums, and fauces and in these sites the lesions were either identical with or very similar to those described as recurrent aphthous or vesicular stomatitis. In each case the well known menstrual exacerbation was noted. In two cases the lesions appeared simultaneously on the vaginal and labial mucosa, and in one case there was a co-existing idiopathic erythema multiforme affecting chiefly the anterior surfaces of both lower limbs. The patients had previously been treated at various times with vitamins and tonics, intravenous arsenicals, chorionic gonadotrophin, mouth washes, and local chemical cauterization, with very disappointing results. The use of benadryl was instituted having in mind the recent suggestion advanced by Zondek and Bromberg (*J. Obstet. Gynaec. Brit. Emp.*, 1947, 54 1) that the condition may sometimes be an allergic manifestation to one or other hormone. The initial dose of the drug employed was 200 mg daily, in each case relief of local pain and tenderness was observed in 24–36 hours, and the ulcers had disappeared within 4–6 days, returning in 1–3 days after withdrawal of the drug. The lesions have since been held in abeyance by an arbitrary dose of—at present—50 mg daily. In these cases familial manifestations of allergy (bronchial asthma, paroxysmal rhinorrhoea) could be traced and it may well be that the mucosal lesions were an unusual expression of an otherwise clinically dormant allergic diathesis.

**D.F.P.**—With reference to our annotation (Oct 16, p 719) on the subject of abdominal distension and D.F.P., Messrs Allen and Hanburys, Ltd (Ware, Herts) inform us that they supply a sterile 0.1% solution of D.F.P. in arachis oil for intramuscular injection, and 0.05 and 0.1% solutions in sterile arachis oil for ophthalmic use. The allied anticholinergic drug, tetraethylpyrophosphate (TEPP) can also be supplied for parenteral and oral administration.

#### Corrections

Sir HENRY DALE writes: In my opening statement at a discussion on the physiological basis of neuromuscular disorders, at the Annual Meeting at Cambridge, a sentence on p 890 of your issue of Nov 20 (line 19) begins: 'It is incompatible, accordingly etc.' The passage should read: 'It is compatible, accordingly'.

Dr J. M. RUSSELL, Divisional Medical Officer of Health for the West Riding of Yorkshire refers to 12 cases of diphtheria notified as from Hoyland Nether Urban District ('Epidemiological Notes' Dec 4 p 1004). This is an error which has now been corrected by the Registrar General. In the Weekly Returns of Infectious Diseases for the week ending Nov 13 sent to the Registrar General the figure 12 appeared under the heading 'Diphtheria' instead of in the next column headed 'Measles'.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: ALLIANCE, LONDON. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1 on receipt of proofs. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: BRIMEDADS, LONDON. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, EUSTON 2111. TELEGRAMS: MEDICINA, LONDON. B.M.A. SCOTTISH OFFICE: 7 Drumheugh Gardens, Edinburgh.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 11 1948

## THE SECRETARY REPORTS

### THE MEDICAL PRACTICES COMMITTEES

There is still a good deal of confusion about the role of the Medical Practices Committees. These bodies, it will be recalled, were appointed by the Minister and the Secretary of State, one for England and Wales and one for Scotland, with certain defined functions. Their main role is to consider applications for inclusion in the medical list of an area after consultation with the local executive council which in turn consults the local medical committee. The only ground on which the Medical Practices Committee can refuse an application is that the number of medical practitioners on the list in the area is already adequate. If the number of candidates exceeds the number required in an area it falls to the Medical Practices Committee to select the successful applicant. Unsuccessful applicants have a right of appeal to the Minister or the Secretary of State, as the case may be. The Medical Practices Committee, in granting an application, is empowered to lay down conditions defining the area in which the successful applicant should practise.

The Minister gave certain assurances to the profession about how the Medical Practices Committee would undertake its work. Certain areas would be deemed and named to be sufficiently doctored. It is convenient to call such named areas "closed areas" and to call other areas, not so named, "open areas". The Minister promised that in open areas the Medical Practices Committee would automatically give approval to applicants for inclusion in the list. In closed areas the Medical Practices Committee might approve an application, everything depending on the circumstances.

It is within the framework of both their legal obligations and the Minister's promise that the Medical Practices Committees are acting. Few areas have so far been designated as closed areas. Information is being gathered on the doctor-adequacy issue, and in a few months' time the committees will have a fairly complete picture of the country as a whole. It may be that with this information available a larger number of areas will be declared closed, but for the moment the number is relatively small.

#### Admission to List

Any practitioner seeking to secure admission to a list in an 'open area' and sending the appropriate form (EC 16) to the local executive council for the area is entitled to have that application forwarded to the Medical Practices Committee and to secure the automatic approval of that body. Neither the local executive council nor the local medical committee is legally entitled to declare an area closed or to hold up an application. This general consideration holds whether or not there is a vacancy caused by death or retirement. In the absence of such a vacancy the procedure is simple and should be swiftly completed. Where however there is a vacancy caused by death or retirement the local executive council should consider first whether the vacancy should be filled. It may decide that it is unnecessary to fill an adequately doctored area or patch the local practitioners being able to undertake the work. If it does follow this course it will seek the approval of the Medical Practices Committee. It may be that a block transfer should be made to a local practitioner already on the list. Bearing in mind that a practitioner already on the list does not need to apply to the Medical Practices Committee for inclusion in that list and that the local executive council is the body which determines to whom a block transfer of the outgoing practitioner's

patients shall be made, the one thing which needs to be referred to the Medical Practices Committee is the issue of whether permission can be given to not filling the vacancy from outside the area.

In other cases the local executive council will decide to advertise, to interview, and to make a provisional selection. While this procedure is being followed it is still open to any practitioner seeking inclusion in the list to send in the appropriate form of application for this purpose (EC 16) whether or not he is an applicant for the vacancy. There is no authority to hold up or to decline the application unless and until the area has been declared closed by the Medical Practices Committee. In due course the local executive council makes a recommendation to the Medical Practices Committee which makes a selection, subject to appeal by the unsuccessful candidate(s) to the Minister. It is open to the Medical Practices Committee at any time before or after it determines the issue to decide whether or not to make the area a closed one. It might for example, decide that, this particular vacancy having been filled, the area is sufficiently doctored. From that moment permission to other applicants is not automatic. But if it does not take this step the position remains that anyone making the appropriate application for inclusion in the list is entitled to automatic acceptance. Incidentally, the form of application for inclusion in the list differs from the form of application for a particular vacancy.

A number of difficulties have arisen. A number of local executive councils have asked for their areas to be declared closed. This can hardly be described as a difficulty, because it is clear that only the Medical Practices Committee can decide such a question, contrary to the belief of some local medical committees.

The form of application for inclusion in the list (EC 16) has caused trouble because it has meant that anyone desiring to put in a valid application has been required to find appropriate professional accommodation first. The question of modifying the form of application so as to require applicants to undertake to obtain suitable accommodation if selected is now being considered.

Occasionally difficulties have arisen because the Medical Practices Committee, with whom the decision lies, has not approved the recommendation of the local executive council. We understand that wherever the procedure is faithfully followed the Medical Practices Committee will approve the decision of the local executive council. But where as has been demonstrated in some cases, the local procedure has been skimmed the Medical Practices Committee may well reach a different decision. In one case the interview of local candidates consisted of a telephone conversation with the clerk of the executive council.

#### Block Transfer of Patients

Another difficulty arises because under existing law the local executive council, not the Medical Practices Committee, is the body which decides to whom the block transfer of patients shall be made in the case of a declared vacancy while it is the Medical Practices Committee, not the local executive council, which determines—subject to appeal to the Minister—who shall fill the vacancy. It could happen therefore that the Medical Practices Committee selects one practitioner and the local executive council makes a block transfer to another practitioner. Most people will agree that these two decisions should be in one pair of hands, and the General Medical Services Committee

at its meeting last week expressed the view that the block transfer of patients should automatically follow the selection by the Medical Practices Committee.

Another and rather unexpected point has emerged. There is no authority under the Act for a local executive council or anybody else to remove from the medical list a practitioner no longer practising in the area if the practitioner has not himself withdrawn his name or the Tribunal has not removed his name. Clearly this is an omission which should be rectified in the amending Bill or regulations.

An impression has been gained that the Medical Practices Committee is concerned with the approval of the employment of assistants. This is true only in so far as the assistant is on the list for the Medical Practices Committee is concerned with all practitioners seeking entrance to the list, whether principals or assistants. The responsibility for approving the employment of assistants rests on the shoulders of the local executive council. Incidentally it is difficult to see why principals should want their assistants to have their names on the list for under the regulations responsibility remains with principals for the acts and omissions of their deputies and their assistants.

It may be that principals with large lists feel that for all the patients to be on their own list will lead them to look to the principal and to the principal only, for their medical service. Apart from this there seems to be no sufficient reason why the assistant should be on the list. Bearing in mind that until the position is altered a practitioner on the list cannot be removed

except on personal request or by the Tribunal, the case against inclusion of assistants in the list is even stronger. Finally it is as necessary as ever it was for a proper agreement or bond to be entered into by an assistant.

#### Public Health Remuneration

For months we have been ready to open negotiations for a new and greatly improved scale of public health remuneration applicable to the whole time officers of local health authorities and local authorities not local health authorities. The negotiating machinery sometimes called the Whitley machinery has been adapted to meet our point that the Medical Functional Council should be autonomous in the field of terms and conditions of service of medical practitioners. The idea is that there should be three subcommittees, one of them a public health subcommittee, the "management side" representing the Departments and the Associations of Local Authorities for England and Wales and Scotland.

The Government interpretation of both Spens Reports has now been issued. Our proposals are ready and we are ready to proceed. We understand that it is the Associations of Local Authorities which are finding some difficulties. One has heard a rumour that these Associations, possibly with one eye on Spens, have been seeking to interview the Chancellor of the Exchequer. We are pressing for negotiations to be opened and it is hoped that it will be possible to do so in the next few weeks.

## National Health Service

### AREAS CLOSED BY M P C

#### FIRST LIST

The Medical Practices Committee has decided that the number of doctors providing general medical services in the following places in England and Wales is adequate

Beer district (Devon)  
Chester  
Iford and Christchurch district (Bournemouth)  
Mayfield district (East Sussex)  
Pelton district (Durham)  
Solva district (Pembrokeshire)

### SPECIAL INDUCEMENTS FUND PROVISIONAL PAYMENTS

The Ministry of Health announces (E.C.L. 108) that applications indicating special hardship will be dealt with forthwith on a provisional basis. In making these provisional payments, claims from sparse v populated areas will in general be given special consideration. When the final decisions are made on the disposal of the fund all the applications will be reviewed to determine if any payments should be increased or others made.

General practitioners applying for a payment from the fund should obtain a form from the local executive council. They will be required to give particulars of their practice income and expenses as well as other details.

### RADIOGRAPHY OF EMIGRANTS NOT A FREE SERVICE

Several regional boards have caused strong resentment among radiologists by instructing them to perform x-ray examinations on emigrants to Canada and Australia as part of their duties in the National Health Service. This is not in accordance with any instruction issued by the Ministry of Health. The x-ray examination of emigrants is a requirement imposed by the Canadian and Australian Governments. It has never been suggested that the ordinary clinical examination of intending emigrants should be performed by general practitioners as part of their terms of service within the National Health Service,

and it is hard to see why radiologists should be treated differently. Representations to this effect have been made to the Ministry of Health.

### CLAIMS FOR COMPENSATION

The closing date for the submission of claims for compensation was Oct. 31. The Minister is empowered to grant extension only where he is satisfied with the reasons for delay. Any doctor who has not sent his claim to the Ministry of Health should do so at once, and his return should be accompanied by a statement of the circumstances which made it impracticable to submit the claim by the due date.

### VISIT TO EAST AFRICA FROM HEADQUARTERS

Dr E. Grey Turner, Assistant Secretary of the Association, is to visit the Kenya, Tanganyika, and Uganda Branches in January, 1949. He is due to arrive at Nairobi on Jan. 6 and to leave for home from Kampala on Jan. 22. The primary purpose of the visit is to discuss with the members of the East African Branches the proposals of the Colonies and Dependencies Committee for the revision of the terms of service of Colonial medical officers in the light of the two Spens Reports. The visit will also afford an opportunity of discussing the proposal of the Kenya Branch that a Royal Commission on Health and Population in the African Colonies should be appointed. The Council of the Kenya Branch has submitted an impressive memorandum on this subject.

### "PART-TIME SPECIALISTS"

Confusion sometimes arises over the use of the term "part time specialist". It is sometimes used to denote consultants or specialists who are partly engaged in general practice or in some other branch of medical practice. It is also used to denote consultants or specialists who are engaged partly in hospital appointments and partly in private practice. Theoretically, the former definition is probably correct, but in practice the latter is the definition most widely accepted. It would be clearer, therefore, if the use of the term "part time specialist" were restricted to consultants and specialists who are not "whole timers"—i.e., have no private practice.

## REMUNERATION OF MEDICAL OFFICERS IN THE ARMED FORCES

The Armed Forces Committee has made considerable progress in its review of the remuneration of medical officers in the armed Forces in relation to the reports of the two Spens Committees. Detailed tables have been compiled comparing the rates of pay and allowances at present in force in the armed Forces with the Spens recommendations, and a subcommittee is thoroughly investigating these tables.

## INTERNATIONAL HOLIDAY EXCHANGES

A number of doctors on the Continent have inquired about holiday exchanges with doctors over here. If Association members who are interested will send particulars to the Secretary he will, so far as is possible, put them in touch with doctors on the Continent or with the appropriate national associations. The Association cannot give any recommendation about the suitability of addresses obtained under this scheme and the final decision to make an exchange rests with the doctors concerned.

## LOCUMS FOR REPRESENTATIVES ATTENDING ASSOCIATION MEETINGS

At the Annual Representative Meeting a proposal was made by the Kensington and Hammersmith Division that members of the Association might volunteer to do part of the daily work of their colleagues attending as their representatives at B.M.A. executive and other important meetings. The proposal was approved by the Representative Body, and the Council now commends the suggestion to the attention of all members.

## AMERICAN FIGHTING FUND

The American Medical Association has voted to ask each of its 140 000 members for \$25 for a fund to oppose any Government-controlled health programme, reports *The Times* (Dec 3). The fund is for 'a nation-wide campaign of education on the progress of American medicine, the importance of the conservation of health, and the advantage of the American system in securing the widespread distribution of a high quality of medical care'.

## GENERAL MEDICAL SERVICES COMMITTEE FIRST MEETING

The first meeting of the General Medical Services Committee, which takes the place of the Insurance Acts Committee and has for the time being the same constitution, was held at B.M.A. House on Dec 3. Sorrow was expressed at the death of two former prominent members of the Insurance Acts Committee—Dr Lionel Picton and Dr Lewis Lilley. The committee then elected Dr S. Wand (Birmingham) chairman. A warm tribute was paid to Dr Gregg the retiring chairman.

The Scottish Subcommittee, the Rural Practitioners Subcommittee (consisting of the members in rural practice with two urban practitioners Dr G. Waring Taylor and Dr Frank Gray), and the subcommittees dealing respectively with remuneration and with terms of service other than remuneration were re-appointed. Another subcommittee was set up to consider the future constitution of the committee itself. At its next meeting the question of the appointment of an executive committee to screen the heavy agenda and take any necessary action between meetings will be considered.

The meeting considered the many motions referred to it by the recent Conference of Local Medical Committees (*Supplement* Dec 4, p 203). These were noted for either immediate or future action or referred for further consideration to an appropriate subcommittee.

Special consideration was given to a motion from the Isle of Wight that a subcommittee should be set up to watch the interests of general practitioners who were members of hospital staffs and part-time specialists. The fear was expressed that this important minority of the profession was in some danger of falling between two stools, the General Medical Services Committee being occupied with general practitioner interests and the Central Consultants and Specialists Committee with the interests of whole-time consultants. It was agreed to propose to the latter committee that a liaison committee of six members, three on each side, should be set up for this purpose.

The three representatives chosen by the General Medical Services Committee, all of them general practitioner specialists were Dr Talbot Rogers, Dr W. D. Steel, and Dr Howie Wood.

## The Role of the Medical Practices Committee

A long discussion took place on the report of a meeting between representatives of the committee and the medical members of the Medical Practices Committees in England and Scotland. One of the principal difficulties is that the function of the Medical Practices Committee is limited to determining applications for inclusion in the list of an executive council, and on the occurrence of a vacancy the decision concerning the transference of the outgoing practitioner's patients is one for determination by the local executive council and the local medical committee. The following proposal was put forward for discussion.

That the Medical Practices Committee should be given power to make decisions on (a) the filling of declared 'vacancies,' (b) the 'block transfer' of the patients of the deceased or retired practitioner, and (c) the application (if any) for the fixed annual payment (basic salary) by the approved applicant.

Dr Gray said that the proposal, from which he dissented, appeared to be that the power of making the selection should be transferred from the local body, which would have knowledge of the local circumstances, to a central body (the Medical Practices Committee). He submitted that on balance it was better to have the succession to a practice and the 'block transfer' of the patients decided locally.

It was stated that, while some local executive councils were doing their work well, a number were apparently failing to make a careful selection of the candidates applying for vacancies.

The committee expressed the view that the filling of declared vacancies should be followed automatically by the 'block transfer' of patients by one and the same body. Further discussion then took place on whether that body should be central or local. A motion that the selection of a practitioner for a vacancy should be made by the local executive council with an appeal to the Minister was lost by a large majority.

The majority opinion of the committee was that matters should stand as they were—that is to say, that the Medical Practices Committee should have the decision, but that a letter should be circulated to local medical committees reminding them of the duties which should be carried out locally. It was also agreed that, should the Medical Practices Committee reverse the decision of a local executive council, that council should have the right of appeal to the Minister. On the question of decisions on applications for basic salary by the approved applicant, it was considered that the first decision should remain at the level of the local medical committee, and that any appeal should lie to the Medical Practices Committee and not to the Minister.

## Remuneration

The chairman said that they were all agreed as to the inadequacy of the remuneration, and he proposed that all the motions from the Conference of Local Medical Committees with other statements from Divisions and individual practitioners, should be passed to the Remuneration Subcommittee. Motions having to do with mileage were referred to the Rural Practitioners and Scottish Subcommittees.

A short discussion took place on the Special Inducements Fund. It was strongly urged in the committee that grants from the Special Inducements Fund should be made in hardship cases, where a practitioner could prove that he had lost a considerable amount of his income under the Act. Dr Stevenson (secretary of the committee) said that the Ministry's representatives stated that they could not at present take the ceiling off the fund because no claims had yet been considered, but they had added that they would make payments on an appropriate scale when application was made, and it was understood that these would be made without regard to the £400,000 ceiling. The Ministry had since issued a circular to local executive councils announcing its decision to deal with applications indicating special hardship on a provisional basis forthwith on the understanding that all applications received would be reviewed when final decisions are made as to the disposal of the Fund to determine what further payments should be made and whether those already made should be increased.

The Association had not been consulted on the form of this circular before its issue.

It was urged that immediate action should be taken with the Ministry and that practitioners should be advised to make their claims. Three or four categories of practitioners were to be considered: those who were suffering hardship and were essential in their area; those who had an abnormal number of chronic sick patients; and others in special circumstances.

It was decided to ask the Public Relations Department to consider how best the true facts of the case could be publicly presented and that a communication be sent to the Ministry protesting that the circular which had been sent to executive councils was not in accordance with the views of the deputation to the Ministry so far as the form of application was concerned.

#### Other Business

Another point which it was decided should be taken up with the Ministry concerned the medical treatment of overseas visitors. Counsel's opinion had been obtained on this subject, and was laid before the committee.

The question of superannuation from the point of view of the proportion of practice expenses to be deducted when an assistant was employed led to a short but highly technical discussion and it was agreed that the Secretary should go to the Ministry and hammer this thing out.

On a resolution from Durham County Local Medical Committee expressing the opinion that the allowance of 14 guineas for the provision of a locum tenens when the practitioner was taking a refresher course was inadequate, it was resolved to press for 17 guineas.

The committee concurred in a recommendation from the Central Consultants and Specialists Committee that in all cases where requests for domiciliary visits are required to be made through the hospital the diagnosis should not be disclosed, and the reason for the request should be confined to the statement that the patient was 'unfit to attend hospital'.

It was agreed to make representations to the Minister with a view to facilities being made available for the midwifery treatment in hospital of a patient by her own doctor even though he were not on the staff of that hospital.

## GENERAL MEDICAL COUNCIL

### WINTER SESSION

The 174th session of the General Medical Council opened on Tuesday, Nov. 23. The President (Sir Herbert Lightfoot Eason) was prevented by illness from attending, and Dr Sydney Smith was elected Acting President.

Dr J. J. O'Donnell was introduced and took his seat as representative of the Apothecaries Hall of Ireland for a term of three years.

#### President's Address

In his address from the Chair, read in his absence, the President began by referring to the death, since the Council last met, of Sir George Newman.

'The role of his service here included seventeen years on the Executive Committee and the same term as a Treasurer and twenty years on the Public Health Committee of which he was Chairman for six years. But no commemoration of him would be adequate without a reference to 'the native wisdom of his advice, to quote the happy expression of my predecessor in the Chair on Sir George's retirement from the Council in 1939. On this wisdom salted as it was with a pungent witness of phrase successive Chairmen of Business and those of whom I was one who were his colleagues as Treasurers drew freely both in our formal deliberations and in the cheerful privacy of the luncheon table.

Senior members of the Council would also have heard with deep regret of the death on Aug. 20 of Professor John Kay Jamieson who represented the University of Leeds from 1928 to 1936. The Council had shown their appreciation of his distinction in the Chair of Anatomy which he adorned in the University and his encyclopaedic knowledge of his subject, by calling him to serve on the Special Committee on the Anatomy Acts in 1929 and of his successful labours as Dean of the

Leeds Medical School by electing him to the Education Committee throughout his term of service and making him a member of the Special Committee on Commonwealth and Foreign Students from 1930 onwards.

They also had to regret that Mr John Charles Flood had again resigned from the Council. He had once more entered a monastic life.

'During his first term of service with us from 1938 to 1943 he was a member of the Pharmacopoeia and Public Health Committees, and when he returned to us in 1946 he served further on the Pharmacopoeia Committee and became a member of the Examination Committee. But we shall remember above all the distinction of his work on the Special Committee on Legislation, which he joined in 1946. The draft Medical Bill owes much to his penetrating intellect and his unsleeping vigilance not only for the rights of the State but for the claims of natural justice in the exercise of professional discipline.

"We shall miss the legal acumen which he always displayed in the consideration of proposals before the Council and in discussion of the decisions which they had to make, and we shall also miss that eloquence in which so many of us on this side of the Irish Sea are lacking. I feel sure that the Council will only wish him peace and happiness in that life which has called to him a second time.'

#### Registrations under the Medical Practitioners and Pharmacists Act

The President said that the number of applications received under the Medical Practitioners and Pharmacists Act, 1947, was just over 1,600, and nearly 1,050 applicants had been registered. The primary business of settling on a permanent basis the position of practitioners who had been temporarily registered during the emergency by virtue of Defence Regulation 32B had been substantially completed. Of just under 1,100 applicants in that category nearly 950 had been registered under Sections 1 and 2 on the receipt by the Council of evidence of satisfactory service in a medical capacity while they were temporarily registered.

Nearly 300 applications had been made by practitioners who had been temporarily registered by virtue of Section 5 of the Polish Resettlement Act, 1947. The number of applications under Section 3, which related primarily to persons who after Sept. 1, 1939, had served in a medical capacity outside the United Kingdom in any of His Majesty's Forces (including Dominion, Indian and Burma Forces) and also to persons whose war service in other circumstances had been considered by Parliament equally deserving of consideration, was just under 140. Of these applicants 57 had been registered under Sections 1 and 3, and a decision covering 52 of the other applicants had been taken by the Executive Committee yesterday. There have been 95 applications under Section 4, which related to persons not within the scope of Sections 2 and 3 who before Aug. 4, 1947, had been permitted to enter or to remain in the United Kingdom in view of circumstances attributable to war, and to certain other persons falling within provisions of Section 5 of the Polish Resettlement Act 1947. Of these applicants 39 had been registered under Sections 1 and 4. About 500 applications remained under consideration. There were nearly 100 cases of Polish practitioners registered by virtue of Defence Regulation 32B in which evidence as to service was not yet complete.

The residue of cases, some of which raise questions of difficulty, is therefore small. Parliament has made the Council responsible under the Act for deciding not only whether service in a medical capacity has been satisfactory, or whether medical qualifications furnish sufficient guarantees of professional competence, but also such unfamiliar points as what is residence in the United Kingdom otherwise than for temporary purpose (Section 1), did a voluntary organization operate in connexion with His Majesty's Forces outside the United Kingdom (Section 3), was the place where an applicant gave professional care to British subjects or British protected persons a place in a country or territory under His Majesty's protection or suzerainty or in which His Majesty had jurisdiction in circumstances specified in the Act (Section 3), what is a sufficient reason or excuse for making a late application (Section 5)?

"The Council are bound to make demands on the patience of applicants whose cases necessarily involve the examination of points such as these, but on the whole the figures show that the back of this very heavy task has been broken since I reported to the Council in my Address in May that the number of registrations under the Act had not reached 200."

### Drug Offences

The Penal Cases Committee had been concerned in the last year or two to note the number of cases reported to the Council of convictions of practitioners for infractions of the Dangerous Drugs Acts and Regulations. While the Council drew a distinction between the purveying of drugs by practitioners to addicts and self-addiction, they felt that members of the profession should realize, to quote the words of a memorandum issued by the Home Office this year, that "in a number of cases doctors who had purchased drugs for the gratification of their own addiction have been convicted of the offences of unlawfully procuring and possessing these drugs." It was therefore clear that the self-administration of dangerous drugs for the gratification of addiction was not one of the necessities for practice for which alone practitioners are authorized to possess and supply such drugs, and the Council felt it right to issue a warning that self-addiction on the part of practitioners might be considered as a grave lapse from the proper standards of professional conduct.

### Disciplinary Cases

Following reports from the Dental Board, the Council considered the case of William Grosart, registered as of Moss Side, Manchester, Dentists Act, 1921, against whom it had been found that he had associated with an unregistered person carrying on the business of dental repair shops who displayed announcements to attract customers, also that he had directly canvassed a person who had entered the shop. The Council directed the Registrar to erase Mr Grosart's name from the *Dentists Register*. A similar course was taken in the case of John Donaldson, registered as of Burns Street, Glasgow, following upon certain convictions for being drunk.

The name of John Henry Port was restored to the *Dentists Register*.

The Council further considered the case of Dr William Francis Hirsch Coulthard, registered as of Aspatia, Carlisle, against whom certain convictions for misdemeanours had been found proved in 1946 and judgment had been postponed for two years. Dr Coulthard now appeared, with testimonials as to his excellent conduct in the interval, and the Council did not see fit to direct the Registrar to erase his name from the *Medical Register*.

The case was heard of Dr Ethel Grundy Toward, registered as of Birtley, Co Durham, who was summoned to appear on the charge that in July last she was convicted at Gateshead of driving a motor car when under the influence of drink or drugs to such an extent as to be incapable of having proper control, and was fined £75 and was disqualified for life from holding a driving licence. It was stated that Mrs Toward had been before the Council on a previous occasion in connexion with a similar charge. On her behalf it was urged that she had taken only a little drink at the end of an extremely busy day, and that she was not at the time of the offence engaged on any professional duty. The Council, after consideration in private, postponed judgment for two years, until November, 1950, but required Dr Toward to attend at the session in November, 1949, with testimonials from professional colleagues and other persons of standing as to her habits and conduct in the interval.

The case of Dr Hugh Boyd Gillespie, registered as of Langside, Glasgow came up for further consideration. In November, 1947, Dr Gillespie had been found by the Council to have been convicted in the previous March at Glasgow of being in charge of a motor vehicle whilst under the influence of drink, and judgment had been postponed for two years, with the requirement that he should come up at the end of one year with testimonials. Dr Gillespie now appeared and produced testimonials and the Council expressed its satisfaction and required his appearance with further testimonials in a year's time, when the period of probation will expire.

The Council considered the case of Frederic Syson, registered as of Tower Gardens Road, London, N 17, who was summoned on the charge that in 1945 at Todmorden petty sessions and also in the same year at Market Bosworth petty sessions he had been convicted of being drunk, and at Market Bosworth petty sessions of embezzling certain small sums of money received

by him on account of the doctors by whom he was employed. For this last offence he was committed for three months' imprisonment on each of the two charges, the sentences to run concurrently, and the recommendation was made that he should be given special treatment. At six previous sessions of the Council this case had been postponed, Dr Syson having been prevented by illness from being present. On this occasion also a medical certificate was put in, stating that he was unable to attend, but the Council decided to proceed with the case in his absence, and, after the facts of the convictions had been stated by the solicitor to the Council, the Council found the convictions proved, but postponed judgment until next session.

The Council concluded its session on Nov 24. The two days were almost entirely occupied with disciplinary inquiries.

The report of the Pharmacopoeia Committee was presented by Dr Campbell. It stated that the number of copies of the *British Pharmacopoeia* 1948, sold since its publication a month or two ago was 31,215. The Pharmacopoeia Commission had restarted its work, various committees had been formed and plans were in progress for the preparation of an *Addendum* which was likely to be published between 1948 and 1953. The next *Pharmacopoeia* in accordance with the Council's decision, would be published five years hence.

Dr Campbell was reappointed by the Council as a member of the Poisons Board under the Pharmacy and Poisons Act, 1933 for a period of three years.

After deliberation *in camera* it was announced that the Council had restored the following names to the *Medical Register*: Alfred Herbert Bartley, David Davidson, Zaky Risk, Graham George Robertson, and Paravasthu Gopaula Sawny.

### Charges Arising from Convictions

The Council considered the case of Reuben Denny, registered as of Twyford Avenue, Acton, who was found to have been convicted of being in charge of a motor vehicle in July last when under the influence of drink.

Dr Denny appeared, and on his behalf it was stated that following the conviction he was admitted to Chiswick House, Pinner, for treatment for acute alcoholism, and a fortnight later left Chiswick House, having recovered. He had been put into touch with 'Alcoholics Anonymous,' an organization for alcoholics who endeavoured to help each other. He had become wholeheartedly interested in this movement, and had not only continued to remain off alcohol entirely but was making every effort, within the organization, to help other people suffering from alcoholism. In the witness box Dr Denny stated that he gave up practice 2½ years ago because of his health. He did not know then, as he did now, what was wrong with him. He believed that his association with 'Alcoholics Anonymous' would enable him to achieve complete sobriety, and he described at the Council's request some of the aims and methods of that organization.

After deliberating in private, the Council, in order to give Dr Denny further opportunity of establishing his resistance to alcohol, postponed judgment for twelve months.

The Council next considered the case of Arthur Mervyn Rhydderch registered as of Chorley Wood, Herts, who was summoned to appear on the charge that on Aug 10 at Wealdstone he was convicted of driving a motor vehicle at Pinner on July 30 whilst under the influence of drink of a similar offence at Pinner on Aug 2, and again of a similar offence at Harrow on Aug 3.

On each charge he had been committed to prison for two months and his driving licence suspended for five years, the terms of imprisonment to be consecutive and the term of suspension to be concurrent. Dr Rhydderch, in reply to his counsel, said that he had been suffering from depression and anxiety over the purchase of a practice and an overwhelming amount of work. Certain medical certificates were put in.

In announcing the decision of the Council, the Acting President (Dr Sydney Smith) said that "convictions of being under the influence of alcohol on three occasions within a few days indicated a lack of control which is as you must realize, discreditable to you and to your profession and might well be dangerous to your patients." The Council postponed judgment for two years but required Dr Rhydderch to attend at their November session, 1949, with certificates as to his conduct in the interval.

The next case was that of William Melrose registered as of St Paul's Square, Liverpool, who was summoned following two convictions of being in charge of a motor-car whilst under the influence of drink, one at Liverpool in October, 1946 and again at St Helens in July 1948.

On his behalf it was stated that he had always been a man of abstemious habits. He had been at the time of these offences the victim of a series of misfortunes, principally illness in his home, and in a state of great nervous strain and tension he took not an unreasonable quantity of alcohol, which had an undue effect upon him. He had been in practice for twenty years in Liverpool and was held in high respect. During the war he was in charge of the first aid post at the Northern Hospital and did most heroic work during the city's heaviest bombardments, and was publicly commended on numerous occasions. Several testimonials from medical men in Liverpool were put in, speaking in high terms of Dr Melrose's character and service.

The Council found the facts of the convictions proved, but, decided to postpone judgment for twelve months.

The Council next considered the case of Archibald Thomas Macmaster Glen registered as of Telford Avenue London, S.W., who appeared following convictions at the County of London Quarter Sessions in May, 1947, and in July, 1948 of being under the influence of drink whilst in charge of a car.

Dr Glen was defended by Mr Norman Richards, instructed by Le Brasseur and Oakley, on behalf of the Medical Protection Society. Three testimonials from fellow doctors and from a local clergyman were put in. On neither of the occasions when the offences were committed was he on professional duty. Counsel referred to the heavy punishment he had already suffered. Following the second conviction he had been ordered to be imprisoned for four months—he had been released from prison only on Oct 6—and his driving licence had been suspended for five years.

The Council postponed judgment for twelve months.

The final case was that of Francis Murray, registered as of Evelyn Street, London, S.E., who appeared on the charge that on June 15 at the Central Criminal Court he had been convicted of assaulting Gillian Baily, thereby occasioning her actual bodily harm and had been bound over under the Probation Act.

Dr Murray was defended by Mr Norman Richards, instructed by Le Brasseur and Oakley, on behalf of the Medical Protection Society. The Solicitor of the Council stated that Mrs Baily was Dr Murray's housekeeper. On May 26, when he was evidently the worse for drink, he accused her of having "given evidence against him" and attacked her, placing his hands around her throat. She got away and ran to the police station, where she collapsed. The detective-inspector in charge of the case gave the Council an account of Dr Murray's drinking habits at the time in question.

After other evidence had been given, Mr Richards, in addressing the Council on Dr Murray's behalf, said that this was a very unusual case. Dr Murray up to 1941 was engaged in a fairly substantial practice, when he began to suffer from fits of depression during which he took more alcohol than was good for him. In one of these fits he had it on his mind, quite wrongly, that Mrs Baily had said something which had worsened his financial troubles. He was now undergoing treatment, and was prepared to give an undertaking that he would not practise until he was certified to do so. He had evidently been under great mental strain for some time.

After a deliberation *in camera* the Council found the offence proved but decided to give Dr Murray an opportunity to overcome the habit which appeared to have conduced to the disgraceful act of which he had been convicted. They postponed judgment on the case for six months.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar.

*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), WallSEND.

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Hutton with Roby, Redditch (restricted to new appointments), Tivdesley.

## Questions Answered

*We publish here the answers to a selection of questions that seem to be of general interest.*

### Fees for Certificates

**Q**—For what medical certificates am I entitled to charge a fee?

**A**—Fees may be charged for all certificates except those issued for the purpose of the following enactments.

Enactment	Purpose for which Certificate is required
Disabled Persons (Employment) Act 1944	To register under the Act
Road Haulage Wages Act 1938	To prove sickness to obtain guaranteed weekly wage
Catering Wages Act 1943	In support of an application for a permit to be employed at a sub-standard wage rate or to obtain guaranteed weekly remuneration or statutory holiday
Councils Act 1945	To claim exemption from a requirement to sit on a jury
Wages (Regulation) Act 1924 to 1947	To claim facilities to vote by post at a parliamentary election
Juries Act 1922	(a) To certify nature of illness and cause of death
Elections and Jurors Act 1945	(b) To certify that a child was born dead in a case of stillbirth
Births and Deaths Registration Acts 1836 to 1926	(a) To certify under Section 55 (8) of the Lunacy Act, 1890 that detention of a person absent on trial is no longer necessary
Lunacy Act 1890	(b) To certify under Section 335 of the Lunacy Act 1890 that a person is incapable of managing his own affairs
Reinstatement in Civil Employment Act 1944	To extend time for making application for reinstatement when prevented by illness
Control of Employment (Directed Persons) Order 1943	In support of claim for changed employment or withdrawal of direction
Defence Regulation 80B Services and Mercantile Marine Disability Pensions Acts	To certify fitness for type of direction
Personal Injuries (Emergency Provisions) Act 1939	(a) To assist in determining a claim to war pension or allowance
Under Defence Regulation 55	(b) To enable proxy to draw pension
(a) Welfare Foods Order 1947	(a) To enable an expectant mother to obtain food benefit or day nurseries to get milk
(b) Food Rationing (General Provisions) Order 1947	(b) To enable invalids to obtain special authorities for supplementary rationed food
(c) (i) Control of Rubber Tyres (No 9) Order 1946	(c) To enable invalids expectant mothers and others to obtain special treatment with regard to goods which are the subject of Government control (rationing or dockets etc)
(ii) Control of Leather (No 2) Order 1944	
(iii) Consumer Rationing Order 1947	
(iv) Utility Furniture (Supply and Acquisition) Consolidation Order 1946	
(v) Import of Goods (Control) Order 1940	
(vi) Apparel and Textile Order 1942	
(vii) Miscellaneous Textiles (Manufacture and Supply) Directions 1942	
Coal Distribution Order 1943	To assist people with young children, old people and invalids in obtaining additional supplies of rationed fuels for heating purposes
Control of Motor Fuel Order 1947	To assist claimants for additional petrol allowances on medical grounds
National Insurance Act 1946	To support a claim to benefit
Insurance (Industrial Injuries) Act 1946	
National Health Services Act 1946	To assist a person in obtaining any of the services provided under the Act, e.g. Supplementary ophthalmic services
Family Allowances Act 1945	To enable proxy to collect allowance
Education Act 1944	As evidence that a child was prevented from attending school by reason of sickness when a parent is summoned or is in risk of being summoned for failure to see that the child attends

### Fees for Vaccinations

**Q**—Why have I received no fees for ten vaccinations carried out since July 5?

**A**—No payments for this purpose are being made pending discussions between the profession and the Ministry and the local authority associations with a view to determining an

appropriate fee for immunizations and vaccinations. These discussions are now in progress. The fees, when determined, will be applied retrospectively from July 5.

#### Pension for Part-time Specialist

**Q**—At the outset of the Service I am likely to be getting £2 000 a year as a part-time specialist. In my last few years I am likely to be doing less hospital work and to be receiving say, £800 a year. Why should my pension be assessed on the lower salary of the last few years of service?

**A**—The pension is not assessed on the last few years of service. It is assessed, like that of the general practitioner, on 1½% of the total net remuneration received throughout the years of service. In the case of a part-time specialist, however, who devotes substantially the whole of his time to his specialist appointments in the Service the Minister may direct that the pension and other benefits shall be assessed on the same basis as that applicable to whole-time salaried officers—i.e., on 1/80th of the average remuneration for each year of contributing service. For this purpose "average remuneration" is the annual average of the remuneration received during the last three years' service.

#### Specialist's Travelling Time

**Q**—I am a surgeon attending several hospitals between ten and twenty miles from my home. Travelling expenses are allowed at the rate of 6d per mile but at present no consideration appears to be given for the time spent in travelling which in my case is 1½ hours per day on an average. Is anything being done about this?

**A**—Yes. The permanent contracts are now under consideration and an allowance both for time and for cost of travelling is being sought. At present it has been agreed that travelling time should be included in the hospital session.

### HEARD AT HEADQUARTERS

#### Embarrassing Publicity

A local paper recently reported the resignation of a doctor from the medical list and stated that his patients would have to choose a new doctor. The information was obtained from the proceedings of an executive council meeting, but the report was misleading because in fact the doctor resigned in order to give all his time to a specialty while remaining in partnership with two doctors who are carrying on general practice. A report such as this could easily embarrass the doctors concerned, and they might be tempted into publishing some explanatory announcement in the Press. It would, however, be ethically unwise to do so. As a last resort, where real distress is expected or experienced, the best course is to send patients a short, purely factual statement (in an envelope) of what has happened.

#### Cafeteria Service Proposed

Members lunching in the Common Room have sometimes complained that it takes too long to get a meal. For some years people have been suggesting that it would be simpler to have a "help yourself" service instead of sitting at a table and being waited on. The Kitchen Subcommittee has therefore recommended that the question of a cafeteria service should be looked into, and at its last meeting it examined designs for a long bar where the food would be kept hot and a member would pick up a plate of whatever he wanted, have additions such as vegetables served on to it at the bar and take it to the table himself. However, it is believed that some members would prefer the present more leisurely club-like atmosphere to be preserved, though it is not known how many they are. The subcommittee also considered providing a bar and snack counter in one corner of the dining room. Probably most members would prefer to have the service speeded up in some such way, and the views of all are welcomed. In any case the Hastings Hall will be opened in due course as a lounge to provide a room for conversation, reading a newspaper, or sinking into a well-earned sleep.

### THE DAIN FUND REPORT OF THE TRUSTEES, 1947-8

The number of inquiries and applications for assistance from the Dain Fund has increased considerably during the past year—nine new cases receiving financial help as against five during the year ending August, 1947. The co-operation of local medical and panel committees has made this possible, and the financial assistance in several cases has been shared by the Dain Fund and a panel committee.

**Case 1**—The widow of a medical practitioner who died suddenly during the summer of 1947 applied for assistance with the education of her twins (a boy and a girl) aged 13 years. The widow herself was in poor health and unable to earn sufficient for the education of these children. The trustees felt that they could not assist in both cases, and as it was understood that the boy was anxious to make medicine his career they decided to help with his education. £50 was given by the Dain Fund and the local medical and panel committee contributed £50. It is hoped that the boy will obtain a scholarship to Epsom College in the near future.

**Case 2**—An elderly medical practitioner applied for assistance with the education of his son, aged 14 years, who is expecting to sit for the School Certificate in the summer of 1949 and who is anxious to take up medicine. The applicant is in receipt of a small pension from Epsom College, but this financial help could not be increased, nor was a grant towards the education of his son available owing to lack of funds. The Trustees felt that this was a deserving case and agreed to allow £75. Here again the local medical and panel committee showed great interest and agreed to assist with a grant of £25. The Trustees will reconsider this case next year should further help be necessary.

**Case 3**—The widow of a general practitioner who, prior to his death, had to give up work for four years owing to ill health applied for a grant to help with the education of her daughter, aged 8 years. She herself was working, and the money she was earning was sufficient to support her daughter and herself but she could not afford the school fees. The local medical and panel committee was approached but had no fund which could assist. The Trustees agreed to grant the sum of £60, and the case will be reviewed next year.

**Case 4**—In 1947 a medical practitioner died, leaving his wife with three children. Application was made for £135 to enable the boy to continue at school and to sit for a classical scholarship to Oxford in the spring of 1949. The Trustees decided that this was a case which should have full assistance, and the total amount of £135 was approved, the money being paid in quarterly instalments of £45 during the year 1948-9. The local medical and panel committee was unable to assist, as they had not a suitable fund.

**Case 5**—A practitioner who had been in practice for eighteen years and who died at the beginning of this year left his widow with two little girls aged 11 and 9 years. The widow asked for £100 to help with their education. The local medical and panel committee was approached and agreed to contribute £50, the Trustees of the Dain Fund also deciding to give £50 and to review the case annually.

**Case 6**—The widow of another practitioner who died this year made application for £100 to assist with the education and maintenance of her daughter aged 14 years and her son aged 11 years. The girl was attending a non-fee-paying school, but the boy's fees amounted to approximately £78 per annum. After considering this case, the Trustees decided to allow the sum requested, the balance between the two amounts to be used for clothing, etc. This case will also be reviewed next year.

**Case 7**—The mother of a boy aged 20 years who had gained a place at the university under the Further Education Scheme applied for assistance with the expenses of his clothing, railway fares, etc., for two years, the sum involved being £40 per annum. The local medical and panel committee was consulted and gladly agreed to give £20 for this year, and the Trustees also decided to grant £20, thus making the £40 requested for the year 1948-9. This case will be reconsidered during the spring of next year.

**Case 8**—Application was made by the widow of a practitioner for assistance with the education of her children, a boy and girl aged 10 years and 12 years, respectively. The sum applied for was £135. The Trustees felt that they could not assist with the education of both these children and that as the boy was only 10 years old he should try for a scholarship at Epsom College. They did, however, agree to help with the education of the girl, and a gift of £81 was granted—the case to be reviewed next year.

**Case 9**—The widow of a practitioner who died in 1940 made application for financial assistance with the education of her daughter aged 8 years. As in a similar case, the mother was working but her income was insufficient to allow her to pay the school fees for the child. The local medical and panel committee contributed £80 to cover these fees, and the Trustees contributed a further £80 to help

with the initial outlay for school equipment, clothing, etc. This case will be reviewed for the Trustees next year.

The Trustees when reconsidering these cases, will have before them a report from the head master or head mistress of the school which the child is attending and also will be informed of any changes in the applicant's financial position.

It will be seen from the above that £561 has been given in grants to new applicants. In addition, £445 has been used in continuing assistance to six cases who have received help in previous years.

A total sum of £1 006 has therefore been allocated throughout the year (September, 1947–August, 1948), a considerable increase over the amount of £565 given in grants last year. It should be noted that the present income from investments amounts to £180 per annum, but it is due to the continued interest and support of both individuals and committees that the Trustees have in fact been able to use their donations to help such a large number of cases up to a total value of over £1 000. The Trustees realize that many of the cases which they have been able to assist will continue to require help throughout the school life of the child concerned, and thus further financial assistance to the Fund is most urgently needed.

Although all inquiries do not result in application for help of a financial nature, advice on many questions is given by the secretary. Certain applications have to be refused or postponed mainly on account of lack of funds, but every effort is made to transfer the applicant to an appropriate benevolent society or association.

It is the desire of the Trustees, while gratefully acknowledging the help received during the year, to appeal once more to the profession for their continued support of the Dain Fund.

H GUY DAIN,

*Chairman of the Trustees*

## Correspondence

### Hospital Costs

SIR—Before the outbreak of war in September 1939, the cost of maintenance of a bed in any one of the best of the voluntary hospitals in London was about £5 per bed per week. I am informed on very good authority that the corresponding cost to day is about £15 per bed per week, and that it is still rising. I have also heard of one hospital where the cost is approaching £20 per bed per week and is still rising. In pre-war days the cost of a bed in the best of the LCC hospitals was also about £5 per bed per week and is now, I understand, nearer £10 per bed per week, and no doubt is also rising.

I do not know how these costs in London hospitals compare with similar hospitals outside the County of London, but, bearing in mind that according to Lord Shepherd (House of Lords, *Hansard* Nov 9) there are 582,000 hospital beds in this country, it becomes obvious that their total cost to day must run into something like £200 million per annum and is still rising. Add to this figure the cost of all the other free medical services provided for the community generally by means of the National Health Service Act 1946 and it will at once become apparent that the total cost will come to a positively staggering amount, probably far in excess of the estimated cost before the Act came into operation on July 5, 1948.

I do not suppose that the Minister of Health worries about the cost of the National Health Service Act, 1946, but I do wonder what our Chancellor of the Exchequer will say when he is faced with the cost of this service for the financial year 1949–50. It might, therefore, be well worth while for such eminently experienced bodies as the Council of King Edward's Hospital Fund for London and the Nuffield Provincial Hospitals Trust to be invited to carry out a thorough survey of hospital costs in order at least to ensure that every effort is being made to combine economy with efficiency in one of the most important branches of the National Health Service. If some drastic steps to reduce hospital costs are not immediately taken the enormous cost may have serious repercussions on the medical services other than hospital work—I am, etc.,

LONDON W 5

FREDERICK MENZIES

### Doctors' Freedom

SIR—I do not like criticizing my superiors but I cannot allow Dr Guy Dain's remarks on the doctors' freedom (*Supplement* Dec 4 p 204) to pass without comment. After all the happenings of this year I have never read such a travesty of the truth.

I have spoken to and received letters from general practitioners all over England, Wales, Scotland, and Northern Ireland, and all I can say is that Dr Guy Dain's conception of freedom must be very different from the rest of us. Freedom to me means everything in life that is worth living for, and it was my grave doubts that the B.M.A. and the Minister of Health would ever give us this freedom in medicine that decided me to resign from general practice in 1944. I know now that it was the wisest decision of my life.

Lord Horder wisely stressed that the Fellowship for Freedom in Medicine was prepared to work with any organization which had this object in view. To accomplish this we must all speak the same language and understand what we mean by freedom in medicine. I disagree absolutely with Dr Guy Dain when he says "if they can assist us in any way to maintain the freedom we have got". One of the first duties of the Fellowship for Freedom in Medicine is to try to regain the freedom which has been lost to us by others—I am, etc.

LONDON N W 3

H V DEAKIN

### Large Lists

SIR—There have been, in my way of thinking, far too many correspondents in your columns advocating doctors to take fewer patients (begrudging the more successful doctors). I can not help feeling it is the old struggle between the "haves" and the "have nots". A practitioner, generally speaking, acquires a big list because he is successful and does his work well, and he deserves suitable remuneration for his efforts. The numbers of patients very soon begin to dwindle if he cannot do his work properly to the satisfaction of his patients. In other words, the number of patients a doctor may have is governed by his ability to look after them.

It is a universal cry to-day, "More pay and less work". A doctor has worked hard to get a good practice, and if he is capable of looking after it, as shown by the fact he can keep his patients, he should not be prevented from doing so. The very spark of life is competition and not security, so let us not lose sight of this—I am, etc.,

SANDHURST KENT

J M BELLAMY

### The Rural Practitioner

SIR,—It has been obvious to me for a long time that the peculiar position of rural practitioners has not been given sufficient consideration, either centrally at Representative Meetings or locally at Branch meetings. There has been a real failure by the leaders of the B.M.A. and by the Secretary of the B.M.A. to appreciate the position, and there is evidence now that the regional hospital boards and central planning authorities are insufficiently informed of the rural practitioners' requirements to make necessary provisions. I would like to deal with the mileage fund as a part of the financial picture. I say a part intentionally, because in some cases even an adequate mileage fund will be insufficient to meet requirements.

The Spens Committee Report stressed the necessity of weighting mileage more heavily to reduce the disparity between the incomes of urban and rural practices. I intend to prove that no attempt has been made to carry out this recommendation and that this disparity will either remain or be increased according to the prevailing conditions which of course vary in different rural practices. The Chairman of Council at the R.M. in Cambridge laboured under the delusion that by increasing the mileage fund from £600,000 to £1.3 million, rural practitioners will be better off than they were prior to the introduction of the new Health Service. This fallacy has already been pointed out by Drs R. M. S. McConaghey and A. J. Edgcombe Rowe (*Supplement* Sept 18 p 125).

What appears to be forgotten is the very important fact that private practice (which has now disappeared) paid a much higher contribution for mileage than the N.H.I. mileage fund. But it is not merely a question of compensating the rural practitioner for the distance travelled, be it 15,000 miles or 30,000 miles per annum, it is a question of paying the rural

practitioner adequately for his work, because he has more work to do per patient on his list than the urban practitioner. When in the distant future health centres are established in urban areas this difference will become even greater. For the same reasons a rural practitioner could not possibly cope with 4,000 patients. The rural practitioner requires to be paid not only according to his annual mileage but also for his extra work.

As one of the representatives who spoke at the Cambridge R.M. in favour of an adequate mileage allowance for rural practitioners I was disarmed by Dr. Dain's assurance, 'The whole position is well in hand—an assurance which was beyond doubt made in good faith, but which the present state of affairs now proves was unjustifiably optimistic. It is quite clear that, so far, the leaders of the B.M.A. have been unable to grasp the real situation. I hasten to declare most emphatically that neither the basic salary (with its horrible stigma) nor the Special Inducement Fund of £400,000 meets the rural practitioner's case, not because of inadequacy, but because the former only operates to the advantage of one type of practice and the latter is at best a charity. Furthermore it is *unreasonable and unfair to deduct the Mileage Fund from the Central Fund*. Why should the urban practitioner require to subsidize the rural practitioner? Strenuous efforts must be made to alter this position. Unless this is done I see little hope of improvement in the mileage payments.

In further support of my argument that the rural practitioner's position has been overlooked, consider the glaring omission of a mileage allowance in rural areas under the Maternity Services Scheme. Under the former scheme for Scotland provision was made for mileage payments whether the patient was an N.H.I. patient or a private patient. Mileage payments are provided for when a doctor is called in by a midwife in the present scheme. Our negotiators have forgotten the rural practitioners. Let our leaders say to themselves in the future 'We shall remember those forgotten men'.

What I have written only touches a few of the problems peculiar to rural practice, there are many more, and I feel that the whole position must be thoroughly investigated centrally and peripherally—I am, etc.,

Auchtermuchty, Fife

HUGH B. MUIR

### One-sided Bargain

SIR,—As a rural practitioner facing bankruptcy under the benefits of the National Health Scheme I feel I should like to raise my one small voice before I am entirely submerged. Last year I had a comfortable income from a small practice, almost entirely private, in a thinly populated country district. With the advent of July 5 some of my patients 'signed on', the majority waited until overtaken by disease and have presented their forms E.C.1 when calling me in, the result being that my list for the first quarter was small and the ensuing cheque did not cover my expenses.

Considering that I fulfilled all the Minister's criteria of hardship rural area thinly populated and a recently inaugurated practice (2½ years) I applied for the basic salary of £300. To my amazement this was rejected by the local executive council, and a letter from the secretary told me that I could probably ascertain the reason for the rejection by perusing the local criteria enclosed on a duplicator slip. After some study I decided that my local committee considered my practice too small to encourage, and by inference, the people here in no need of a doctor. I appealed to the Minister a month ago and received a courteous reply but no more concrete result of interest. The result is that I am now working, and working hard for charity and my conscience, and living by the kindness of my bank manager (at 4%).

Another point I raised with the Minister was the expense involved in using the telephone. He replied that that was my responsibility and that allowance for such expenses had been made in assessing remuneration. Pray to observe the fantastic injustice of the fact that the rate of remuneration is the same for the town practitioner with a maximum list whose telephone calls cost 1d for ambulance or hospital as for the isolated country doctor whose call for an ambulance costs 6d and to talk to a hospital or specialist costs 10d or 1s.

I have honestly fulfilled my part of the contract and give the same service as when I was paid for it, but am disgusted to

think that a Government whose professed policy is a living wage for all its servants should, with the connivance of our own medical leaders, have so dishonourably disregarded its bargain—I am, etc.,

Burwash, Sussex

VERNA KENDALL

### Fellowship for Freedom in Medicine

SIR,—You were good enough to print a full account (*Supplement*, Nov. 20, p. 180) of the formation of this Fellowship under the chairmanship of Lord Horder. May we therefore ask you to state that all inquiries, including applications for membership, should be made to the Honorary Secretary, 40, Westminster Palace Gardens, Artillery Row, SW 1?—We are, etc.,

G. H. ROSSDALE

E. C. WARNER,  
Hon. Secs.

### Battle of Certificates

SIR,—It would seem that the battle of the certificates has started. Many of us predicted that after July 5 the already onerous business of signing certificates would occupy more and more time. I am now informed by the manager of the local office of the Ministry of National Insurance that "certificates have to be sent in consecutive weeks, each week beginning Sunday midnight," and he adds that a weekly certificate completed on a Monday should be followed by one completed on the following Saturday.

In my case most patients call for their certificates on Monday (market day), which is the only day on which there is an adequate bus service to bring them to the surgery. It would seem therefore that I must either put a false date on all certificates or else put aside the whole of each Saturday for certificate signing. Surely the wording of the N.H.S. certificates is such that strict adherence to the 7-day period is unnecessary? Some latitude should be allowed both for the sake of the patient and the doctor. Heaven knows that our lot is not a happy one at the moment, and such official nonsense helps nobody—I am, etc.,

Spilsby, Lincs

C. E. FRISKNEY

\*\* The position is that the second certificate (the first intermediate certificate) must be given within seven days of the first certificate. Thereafter, intermediate certificates must be given "for every contribution week during the continuance of the incapacity" except in cases of prolonged illness, when the doctor is entitled to issue certificates at longer intervals. 'Contribution week' is defined as "a period of seven days commencing from midnight between Sunday and Monday". Accordingly, a doctor may give a second or succeeding intermediate certificate on Monday and the next one on the following Sunday week without contravening the certification rules.—ED, B.M.J.

### Ophthalmic Work in N.H.S.

SIR,—May I be allowed to bring forward two aspects of eye work under the National Health Service?

First, the question of remuneration of oculists doing school clinic work in view of the recent pronouncement of the Ministry of Education reported in the *Supplement* of Nov. 6 (p. 161). It has been negotiated centrally that refractions in school clinics are to be paid for at the rate of 12s. 6d. per child, and this amount will be paid to oculists by the local executive councils. At the same time we are informed that oculists are to be paid on sessional rates at £6.6s. for a three-hour session. If, for example, eighteen children are seen in this period, £11.5s. will have been earned, and the oculist is invited to claim this sum and to return the difference between that and the sessional rate of £6.6s. to the local authority concerned. This seems to me a curious example of officialdom and grossly unfair to the oculist, who gives the local authority a direct profit on every clinic he holds. It is no justification to state that the payment is for refractions only and that the fee of 12s. 6d. would not be payable in all cases. Every school-child must have his refraction worked out whether or not he suffers from some ocular defect such as squint, blepharitis, etc.

Secondly, it may be noted that, though the oculist is paid 12s. 6d. instead of the usual £1.11s. 6d. for a refraction, the

optician suffers no reduction and still receives 25s for every pair of school child's glasses he dispenses. It is some comfort to know however, that he is limited to the oculist's prescription and is not permitted the multiplicity of glasses ordered in ordinary National Health Service work when a sight testing optician can, and does, order several pairs of glasses for a single patient and receives 25s for each pair he finds it "advisable" for the patient to have—I am, etc.,

Tunbridge Wells Kent.

H M SYMONS

\* \* As soon as necessary arrangements can be made—and these are already in progress—dispensing work in connexion with the school eye service will be undertaken entirely through the hospital service. Hospitals have been asked to recruit dispensing opticians to their staffs for this purpose—ED B M J

### Opticians and Home Visiting

SIR—Under the Supplementary Ophthalmic Services there is no special provision for domiciliary visits, but the ophthalmic medical practitioner or ophthalmic optician carrying out such a visit is permitted to make a reasonable extra charge to the patient. The difficulty is that many bedridden patients tend to be old and in poor circumstances, and in such cases it is invidious to make a charge to the patient that would not be levied on others better fitted to pay. Under such circumstances the majority of ophthalmic opticians visit bedridden patients and make no extra charge for the mileage, inconvenience, and loss of time. I know that Dr H C Saksena's experience (*Supplement* Nov 6, p 164) is exceptional—I am, etc.,

S BLACK,

Association of Optical Practitioners

Director Information Bureau

### Remedy for Abuses

SIR—I would like to remind doctors whose patients grossly abuse their position that we now have an effective remedy. We have only to request the executive council to remove the offender's name from our list. I believe that it will usually suffice if one unhesitatingly tells a sinner that one proposes to take this course—I am, etc.,

Sedbergh Yorks

H THISTLETHWAITE

### Tell the Public

SIR—I have just read the leading article under the heading NHS (Nov 13, p 864). I applaud the statements made and the sentiment expressed that 'it is up to the Government to meet promptly the causes of discontent' among the medical profession. I realize also that the B M A have had a difficult and often thankless task in the stormy birth of the NHS and I hesitate to criticize. But why print such an article in the *B M J* to be read by doctors who already know the facts only too well? The place for it is in the national press.

While conditions are still fluid it is of paramount importance that the question of remuneration of the whole profession be reviewed and agreed upon. Let us not be mealy mouthed about money. From the newly qualified to the veteran the unfair financial return rankles and prevents the best work being done. Yet it is obvious that the large mass of the public are quite unaware of this position. Many of them think that doctors are better off financially than ever before. Let us not emuliate the nation in the feebleness of its propaganda abroad. Tell the public the facts. Let them be read in everything from the *Daily Mirror* to *The Times* (this is surely not beyond our powers) and let us have the people on our side—I am, etc.,

Sockton Heath Lancs

J K W MORRICE

### A Matter of Conscience

SIR—A sentence in the leading article on the National Health Service (Nov 13 p 864) is so naive that I am still wondering whether I have read it aright. It runs '... it seems that a large proportion of those who might well have been expected to pay direct for their medical treatment have in fact asked to be cared for under the National Health Service scheme'. When you compel a man to pay weekly a subscription of appreciable size against his will and possibly, against his judgment he has two lines of action open to him—to cut his losses and ignore that of which he does not approve, or to

make as much out of it as he can. Obviously the last is the most popular course with "the vermin".

Now there is a question I should like to ask and one which I have not yet seen considered. If a man feels sincerely and deeply (as I do) that the NHS (and other forms of nationalization) is biologically and ethically detrimental to the State and the citizens—a theme argued and developed in an essay published in the *Journal of the Medical Association of Erie* 1948, 23, p 25—how can he reconcile his conscience with contributing money to assist it more especially if the money is not being forcibly deducted from wages? In war the existence of a conscience is conceded by the Government and deferred to to some extent, but in this matter there is no choice except between conscience and freedom—or conscience and bankruptcy. A doctor has some opportunity of standing by his convictions, a patient has none yet the function of the State according to Aristotle, is the moral advancement of the citizen—or is Aristotle out of date?—I am, etc.,

Dublin

MICHAEL DILLON

### Liverpool Registrars' Group

SIR,—A Registrars Group has been formed in the Liverpool Region to discuss conditions of service under the National Health Scheme. We would be interested to hear if such groups have been formed in other regions, as we consider the interchange of ideas on this subject would be of great value—We are, etc.,

Ingleside Hightown Nr Liverpool

W H R COOK

C S MCKENDRICK

### Private Patients and Medicines

SIR—It is with extreme regret that I read in the report of the Proceedings of Council of Oct 27 (*Supplement* Nov 6, p 157) the remarks made by the Chairman of the Representative Body, Dr Gregg, in regard to private patients and medicines. His remarks suggest that no active steps will be taken at present to rectify the injustice of the private patient not being allowed free medicine. Surely this situation has now been accepted only as a result of the Minister's interpretation of the Act, which the lawyers may interpret otherwise.

My more serious criticism of his remarks is that, in clarifying the position of the Government on this matter, he mentions the absence of control by the Government over the private doctor's prescribing. If control is necessary in regard to prescribing by the private doctor, why is he allowed to issue certificates of all kinds—e.g., sickness benefit, sight testing—and allowed to make use of State laboratories and x ray departments, all involving very much larger expenditure than prescribing?

If we are to condone the Government's view in regard to prescribing for the private patient, there are only a few more moves to be made before the private patient will not be allowed other facilities which cost the State money because there is no control over his doctor—in other words a gradual boycotting of private practice will follow—I am, etc.,

Sevenoaks Kent

D E YARROW

### Appointment to Hospital Staff

SIR—We should like to draw your attention to, and enter a protest against, the manner in which a surgical colleague was elected to the visiting staff of a London hospital. While freely admitting that no better choice could have been made, it must be conceded that the manner of the election could not have been worse.

Thus the regional board advertised the appointment of a surgeon on Oct 8, 1948, the vacancy having occurred as the result of death in July, 1948. The applications were sent by the senior administrative medical officer of the regional hospital board to the lay secretary of the Group Medical Advisory Council on Oct 14, 1948, with the request that that Council should suggest a short list of no more than five names by Oct 16. The secretary replied that the Council was meeting on Oct 18 and it was therefore agreed that the short list should be made on that day and sent to the regional board by messenger. On Oct 18 the applications were considered, but no candidates were available for the interview and five names were selected,

but only after two representatives of the hospital, neither of whom was a surgeon had protested at the unwisdom of making a choice among people whom they had not had the opportunity of seeing. A protest was also made that no surgical representative from the hospital would be co-opted to the selecting committee.

Our present protest is being made because neither the applications nor the applicants were at any time brought before the medical committee of the hospital—We are, etc.,

GEORGE ROSSDALE

A PINEY

T MEYRICK THOMAS

London W 1

### Basic Salary

SIR—Will you allow me to point out to Dr Roy F Fairweather (*Supplement* Nov 27, p 196) that I accepted service under the Health Act after very full consideration of the alternatives in the method of remuneration offered me by the Minister? At the time I accepted service I gave notice of the method of remuneration acceptable to me. I am not interested in the influences which persuaded the Minister to dishonour his undertaking, upon which I joined the Service, nor am I in the least surprised that he should do something which I would consider highly dishonourable were it done by me.

What conceivable excuse has the Minister, having dishonoured his contract with me, for saying that the honouring of his side of a purely professional contract now depends upon my private resources? Perhaps my colleagues will persuade the Minister before March 31 next that my compensation should be withheld on the grounds that I have sufficient private means to prevent my becoming a burden on the State. That would leave more in the pool for them—I am, etc.,

London SE 24

KENNETH MCFADYEAN

### Estimate of Income

SIR—Your leading article entitled "NHS" (Nov 13 p 864) repeats the assertion made by Dr Charles Hill (*Supplement* Oct 23, p 145) that the pre-war income of the general practitioners amounted to £28 million—he said "rather more than". So bold a statement of fact should be accompanied by detailed information as to its basis. Actuaries tell me that no statistician would claim it as any more than an estimate, as liable to fallacy as the polls which prophesied Mr Dewey's election. The deduction that NHS nearly doubles his income is poor comfort to the practitioner who knows the state of his bank balance. It will provide useful ammunition for the Minister of Health—I am, etc.,

Worthing Sussex

A S MORTON PALMER

\* \* The figure of £28 000 000 was determined by an eminent statistician from information given by a sample of general practitioners taken with the usual precautions. A statistical statement made on existing data is not comparable to one made on opinions about future events such as an election—ED B M J

### Withhold Certificates

SIR—I am an advocate of a National Health Service. I feel that we of the profession can make this a good service if we get co-operation from all sides. Being a practitioner in a fairly well populated area although my income will in all probability fall, I will not be in penury, but I am alarmed at the conditions of the general practitioner in country districts and do feel that the British Medical Association should take much stronger action than they have done in the past.

Strike action is entirely out of the question but there is no reason that I can see why we should not state to the Minister that unless our brethren in the country are treated more generously—and that quickly—then we as a profession will withhold all certificates from patients. It is well known that we are working to capacity now, and if this action were taken by the town doctors for the sake of those in the country I am sure that we would get the sympathy not only of the public but of the majority of the Members of Parliament. I have never flown into print before but I feel that this injustice should cease forthwith—I am, etc.

M. A. Bester

ROBT B H FAICHNEY

## POINTS FROM LETTERS

### Loss of Freedom by M O S H

Dr J KATZ (Accrington, Lancs) writes. The tragedy of medical officers of health consists in the loss of freedom of settling in practice, including the National Health Service. We were deprived of the only weapon which would have helped us in the struggle to bring the salary scales of medical officers of health to a level in keeping with those of other members of the profession—namely, the most effective weapon to leave (if desired and convenient) the public health service and to establish ourselves as practitioners in the place of our own choice in accordance with the state existing prior to the appointed day—July 5, 1948.

### Maternity Form

Dr J A HOOKER (Cotes, I O W) writes. Would it not be a good idea to enlarge the claim form for maternity work (EC 24) so that clinical details of the antenatal period, confinement and puerperium could be included, so providing under one cover all the information required for filling in the claim and at the same time affording a permanent record of the case?

### Up to the B M A

Dr J B SPEARMAN (Gillingham, Dorset) writes. The concluding words of your leading article on the NHS (Nov 13, p 864) read "and it is up to the Government to meet promptly the causes of discontent which now prevail." Surely it is up to the Council of the B M A to insist in no uncertain terms that the Government does so act—and without delay.

### Prescribing by Retired Doctors

Dr J K HOWLETT (Old Hunstanton, Norfolk) writes. I agree with Dr N J C Rutherford (*Supplement*, Nov 6, p 167) that prescription pads under the NHS should be issued to retired doctors. My wife and I are both invalids and have no car. We are both on the list of a doctor whose surgery is about three miles from our house. Suffering from arteriosclerosis and frequent angina, I am in constant need of tablets and capsules. To send for prescriptions from my local doctor is giving him and myself unnecessary trouble and should not be enforced on one who has had 45 years' experience in general practice.

### Holiday Rota

Dr P D GRIFFITHS (Kidderminster, Worcs) writes. The shortage of doctors will soon be made much more acute by illness and early death if the fantastic working hours are not compensated by sufficient holidays. Many G P's work 70 or more hours a week—every week-end and bank holiday. They are now lucky if they can find a locum to give them a fortnight's holiday. This is asking for trouble. If holidays were "staggered" by mutual arrangement, could not the doctors' patients be allowed to consult any other doctor they choose? Obviously a locum is not forthcoming for every G P to take a holiday, and if one is available he is in expensive luxury. A partnership does not solve the problem, for it is useless taking two weeks' holiday and returning to two weeks' double work.

### Prompt Payment

Dr L J SHEIL (Harlow, Essex) writes. As I was born in 1887 I cannot qualify for a pension under the present NHS regulations. I do feel that it is now time we had a concrete business proposition to work on. I do not know how much I am paid per head for my patients. The mileage allowance has not been specified. Monthly payments should be paid and not quarterly as at present, all other Government work is paid monthly. Domiciliary midwifery fees should be paid promptly. Some recompense should be made to us doctors of 60 and over for the years we have worked N H I schemes. I know all these points have already been raised in the *Journal*, but I do feel that one more signature should reach the B M A Negotiating Committee to make them take some action with the Minister.

The Occupational Health Committee hopes to find opportunities of useful co-operation with the Panel on Human Factors of the Cabinet Committee on Industrial Productivity. In the Section of Occupational Health at the Annual Meeting of the Association in Cambridge, the Chairman of the Panel Sir George Schuster, referred to the contribution to productivity that doctors in industry can make through human relations. Sir George, accompanied by other members of this Panel attended the recent meeting of the Committee for a preliminary discussion of methods whereby the special experience of doctors working in the industrial field might be brought to the knowledge of the Panel.

## THE INCIDENCE AND TREATMENT OF INFECTIVE EAR DISEASE IN FACTORY EMPLOYEES\*

BY

COLIN M JOHNSTON, M S†

Sir,—Will you allow me to point out that the Health Act after 1936 made it the duty of the Ministry of Labour to take steps to prevent the use of wastage of man-power in the late war disease of the ear. Thus during February and March 1945, at four large military hospitals in the United Kingdom, 1,956 out-patients were seen, of whom no fewer than 1,270 (65%) were suffering from diseases of the ear, nose, or throat. Of these 1,517 cases approximately 1,000 (66%) were due to all forms of disease of the ear, of which 33% (33%) were due to chronic suppurative otitis media. It was shown that chronic ear disease caused a loss of fighting man-power in time of emergency. This was good reason for believing that this serious state of affairs had its basis in the high rate of ear disease prevalent in the civilian population, and this was strikingly confirmed by the results of a study of the records of the Ministry of Labour and National Service Boards.

The study revealed that just over 2% of the recruits examined were rejected on account of chronic ear disease, while 10% of the recruits of the ear were responsible for 10% of the total number rejected from all causes. Now chronic ear diseases, in particular CSOM, are well known as potent causes of inefficiency, invalidism, or even death. Occupational groups such as food manufacturers, shops, the General Post Office, and life assurance companies recognize their importance and may penalize the sufferer by refusing him employment or insurance as the case may be. The high incidence of the disease emphasized by wartime experience, therefore demanded consideration in the planning of the health services of the country, and the present study of the incidence, prevention, and treatment of chronic ear disease in a sample of the civilian population owes its inception and design to the committee of the Medical Research Council appointed to advise upon the medical and surgical treatment of deafness.

Much information about ear disease in children had already been obtained from the school medical services. The methods and results of treatment of the disease in hospital practice were well known among otologists, but little knowledge of the incidence in the adult population was available, and there was general dissatisfaction about the results of treatment. The work carried out during the war by otologists in the armed Forces and the civilian emergency medical service demonstrated on a large scale the validity of previous observations. These showed that good results were obtainable with conservative treatment. Thus by regular daily treatment Banham§ was able to

obtain a dry ear in 82.5% of 200 cases of chronic suppurative otitis media occurring in R A F personnel. This result strongly suggested that the high incidence of chronic suppurative otitis media in the civilian population is mainly due to neglect—a neglect which arises in large part from the patient's inability, for economic reasons, to attend regularly for treatment. Attendance at the panel doctor's surgery means that patients often have to leave the office or factory before completion of the day's work and then wait for several hours before being examined. Owing to pressure of work the practitioner is unable to do more than prescribe ear drops, which usually fail to cure the condition. Attendance at hospital for specialist advice and treatment also entails absence from work, which may cause very considerable loss of wages. Even when facilities are available at the hospital for treatment after the patient's working hours—and this is exceptional—there will be a considerable interference with leisure. The patient may be prepared to sacrifice wages or leisure for short periods or for painful and disabling conditions, but the slight symptoms of most cases of chronic ear disease seldom impel him to endure the discomforts and losses resulting from a course of treatment which may extend over several months.

The only reasonable alternative would appear to be treatment given at or near the place of work. An ear-treatment clinic organized at the factory or office would obviate the time spent in travelling to the hospital and would enable the sufferer to obtain regular treatment during his working hours. An industrial area containing large factories would provide the necessary clinical material, and it was accordingly decided to investigate the possibilities of treating chronic suppurative otitis media in factory clinics situated in such an area.

After negotiations with the Industrial Health Research Board and a group of industrial medical officers I was appointed as a full-time otologist to carry out an investigation in factory clinics in the Birmingham area.

The investigation falls into two sections. First, a survey was made to determine the incidence of ear disease in the population of the factories concerned. Secondly an attempt was made by means of a field experiment to determine the value of the factory clinics in treating ear diseases in the associated population. The work done under both of these headings forms the subject of the present report.

### Introductory Note on Factory Medical Services

Before the late war many factories employed a trained nurse and some a part-time or whole-time medical officer. During the war the large influx of unskilled labour and the longer working hours made an extension of the factory medical service essential, and many of the larger factories

\*An abridged version of the report presented by the Medical Committee to Advise on Medical and Surgical Problems of Diseases of the Ear of the Medical Research Council.  
†In receipt of a whole-time grant from the Medical Research Council.  
§The above data were obtained from a report on 'Chronic Suppurative Otitis Media in the Army' presented by Brigadier M L Banham to the Medical Research Council (MSD 17).

developed a well equipped medical organization directed by one or more full-time medical officers and staffed by State-registered nurses. Their value in safeguarding the health of employees has been proved, and the retention of industrial health services in the future is probably assured. In a few factory clinics the conditions equal those of a hospital casualty department and a diagnostic x-ray plant is available. Ophthalmic, dental, chiropody, and physiotherapy treatments are available, and are conducted by visiting specialists or by trained staff. Treatment and advice by the specialist are by appointment, during working hours. Workers appreciate this, and managements are satisfied that the results obtained warrant both the small capital expenditure entailed and the small loss of the worker's productive time.

Where the factory covers a large area the medical organization usually includes a central medical department with one or more dressing stations, in order that the employee shall not have to walk too great a distance from his place of work. This is of value in facilitating the early treatment of minor cuts and preventing sepsis, and where the condition requires daily or more frequent attention less time will be lost from productive work.

In the present conditions of the five day working week factories where continuous processes are not employed close at week-ends and during public and works holidays. The medical department will also be closed during those times and continuity of medical treatment interrupted. In factories where night work is carried out the dressing station may be manned by a male nursing orderly who, though well experienced, has had only first-aid training.

Thus apart from the drawbacks already mentioned, the factory medical services have all necessary facilities for the treatment of minor complaints, and many of the difficulties expressed by sufferers in obtaining treatment elsewhere are thereby overcome.

It should be stressed that the primary function of the factory medical service is to maintain the working efficiency of the employee and to prevent accidents and ill-health occurring at the place of work. It is not held that infective ear disease is an industrial hazard, but it may be detrimental to effective working capacity. Alleviation will therefore come within the purview of the industrial health service, but from the point of view of the factory management the loss of production caused by the time spent on treatment must be balanced by an increased efficiency for work. This should be demonstrated by a decrease in absence due to sickness.

### SECTION I

#### Survey to Ascertain the Incidence of Ear Disease in the Factory Population

In order to gain an estimate of the incidence of chronic infective disease of the ear in the factory population a survey has been conducted of a random sample of the workers in four factories in Birmingham.

Experience gained during the survey confirmed the opinion previously held, that statements by individuals regarding not only the degree but even the presence or absence of ear symptoms were inaccurate. Thus several individuals, after stating that their ears were healthy, expressed surprise on being shown pus removed from their ear. A person's assessment of the acuity of his hearing varied from those professing some deafness, when the hearing was found to be normal to rough testing, to the others who severely deaf will only with reluctance admit even a slight loss of hearing. It was therefore essential for the purposes of accuracy to examine the external auditory meatus with an aural speculum and adequate lighting.

Care was taken to explain the objects of the survey before permission was asked to examine the ears. Out of 1,902 individuals examined only 14 refused to co-operate, and there was reason to suspect that a proportion of these suffered from ear disease and for a variety of reasons did not wish to divulge the fact. Owing to the limitations imposed on the length of the examination due to the necessity for avoiding interference with factory production, cerumen could not in all cases be removed nor could an attempt be made to assess the cause or degree of any deafness. The presence of cerumen was noted if in an amount sufficient to obscure a view of the ear-drum.

### Results

The survey was conducted over a period of 13 months from August, 1946, to September, 1947. Table I shows the incidence of ear disease in the total sample examined. It may be noted that the numbers refer to the individuals affected and not to the number of ears.

TABLE I—Incidence of Ear Disease in the Total Sample

Individuals examined	No	Percentage Incidence
	1 902	100
1 Cerumen		
Unilateral	239	47.5
Bilateral	236	
2 Otitis externa		
Membrana tympani intact	49	2.6
3 Scarring without perforation of the membrana tympani		
Unilateral	153	11.6
Bilateral	67	
4 Dry perforations of the membrana tympani		
Unilateral	28	31
Bilateral	3	
5 Active suppurative otitis media		
Unilateral	48	62
Bilateral	14	
6 Healed cortical mastoidectomy		
Middle ear dry	16	19
Unilateral	1	
Bilateral	2	
Middle ear infected	7	
7 Healed radical mastoidectomy		
Unilateral	339	0.4
8 Otitis media active and healed (Sections 3, 4, 5, 6 and 7)		17.8
9 Bilateral otitis media Active in one ear or both	19	2.7
10 Bilateral otitis media Healed in both ears	58	4.6
Healed mastoid operations (Sections 6 and 7)	26	1.4

Table II shows in a summarized form the incidence of ear disease in different age and sex groups.

TABLE II—Incidence of Age and Sex Groups in Sample

	Male	Female	Total	Percentage
Under 20	249	69	318	16.7
20 to 29	369	140	509	26.5
30 to 39	364	45	409	21.5
40 to 49	292	37	329	17.4
50 to 59	211	17	228	12.1
60 and over	104	5	109	5.7
Total	1 589	313	1 902	100

### SECTION II

#### Organization of Factory Ear-treatment Service

The organization of the factory medical department designed to suit the needs of the group it serves, differs in many ways from that of a hospital. An ear-treatment service must therefore adapt itself to the altered conditions, and, although in this investigation the treatment has been similar to that of the hospital, some modifications have had to be made in the light of experience. As these modifications have had an effect on the results of treatment they should be considered when comparing results with those derived from hospital practice. A permanent basis for an ear-treatment service would doubtless diminish, but not abolish, these differences.

Facilities available in factory medical departments have been found adequate for the treatment of chronic ear disease.

with the exception of certain deficiencies. Intermittency of treatment, the lack of certain diagnostic aids, and to some extent lack of the greatest possible skill in treatment by the nursing staff have militated against full efficiency. Discussion on these latter points will be found in the section on the treatment methods employed for chronic suppurative otitis media.

### Results of Factory Ear-treatment Service

The results reported in this paper have been derived from work carried out in seven large factories situated in the city of Birmingham, employing in all 51,900 employees. A considerable proportion of these workers were not natives of Birmingham but had spent their childhood elsewhere in Great Britain or in Eire. All these factories have well-equipped and efficient medical departments with the facilities already outlined.

Table III shows the clinical conditions encountered. An analysis of these cases and the results of their treatment, will now be considered.

TABLE III—Clinical Conditions Encountered

Condition	No of Patients
Cerumen	255
Otitis externa	389
Other conditions of pinna and meatus	24
Acute otitis media	26
Chronic suppurative otitis media	274
Healed otitis media	249
Healed cortical mastoidectomy	26
Healed radical mastoidectomy	44
Eustachian obstruction	65
Clinical otosclerosis	26
Conductive and mixed deafness of unknown aetiology	20
Perceptive deafness	117
Conditions of ear not already classified	32
Conditions of the nose and throat	78
Suspected disease of ear, nose or throat—nothing abnormal found	62
Other conditions of head and neck	24

#### Cerumen

These patients were referred to the otologist because of pain or deafness, and removal of the cerumen revealed no other abnormality of the ear. Cases where another ear condition was found have not been included under this heading.

Most cases of cerumen coming for treatment at the factory surgery are referred by the nursing staff to the panel doctor in charge of the case. Some for one reason or another prefer to obtain their treatment in the factory surgery and are dealt with by the nursing staff. A few, because of pain or difficulty of removal of the cerumen were referred to the otologist. 237 patients were seen. Six examples of keratosis obturans were observed. The meatus was restored to normal in each case as a result of treatment.

#### Otitis Externa

**Furunculosis**—The majority of the cases were solitary and not followed by a subsequent attack. The condition was observed more commonly in young adults, usually female, or in individuals who had a slight abnormality of the meatus. Thus in the opposite meatus the cerumen was scanty and stiffer in consistency than the normal, or there was an absence of cerumen with a few dry epithelial scales.

**Treatment**—Any epithelial debris and pus lying in the meatus were removed by the otologist as a preliminary measure. When a mild diathermy (inductiotherapy) was given and relieved the pain in under 48 hours. Alternatively ichthylol preparations were applied on a gauze wick until the pain subsided. In an attempt to prevent recurrences drops of ung. hyd. nit. dil. in liquid paraffin 1 in 8 were instilled daily for a week or longer.

In no case observed was it necessary to employ vaccine therapy or such preparations as colloidal manganese.

#### Acute Otitis Externa

This condition was more often seen as an exacerbation of a chronic condition but it also occurred *de novo*. The latter condition only will be discussed in this section.

In some cases a history of previous attacks was present. The initial attack was occasionally caused by furunculosis or occurred during service in the armed Forces. The entrance

of infected water into the meatus, as in sea or fresh-water bathing or washing, appeared to precipitate an attack in some cases, while the constitutional effect of acute coryza, dietary indiscretion, or dental extraction in the causation was observed. In others an active chronic suppurative otitis media was present. Otitis externa occurring during the course of treatment of otitis media was a troublesome complication and in the majority of cases followed the use of insufflations containing sulphathiazide. It appeared to be a true sensitization, as the previous continual use of such a preparation in the ear was without ill effect. Less often otitis externa followed the use of spirit drops or iodine and boric powder insufflations.

In the most severe cases the meatal lesion spread over the lateral surface of the pinna and involved the surrounding skin of the cheek and neck, forming an acute weeping eczema.

**Treatment**—Care was taken at the first and subsequent examinations to remove scrupulously all pus and epithelial debris from the meatus, paying particular attention to the anterior and inferior parts of the junction between the meatal wall and the tympanic membrane. Afterwards the ear was mopped out daily with dry cotton-wool-tipped probes by the nursing staff.

Of the medicaments used, 1% aqueous gentian violet solution, 50% spirit containing  $\frac{1}{2}$ % gentian violet, aluminium acetate solution 4%, and calamine lotion were found to be of the most use. Gentian violet very rarely caused exacerbation and appeared to be more effective when combined with spirit as above, but in some cases resolution was slow. Aluminium acetate applied on  $\frac{1}{2}$ -in (1.25 cm) wide ribbon gauze packs gave excellent results in some cases, but occasionally failed or, worse, caused severe exacerbation. For lesions of the pinna gentian violet, while giving good results, was disfiguring to the patient. Calamine lotion could be satisfactorily substituted in most cases but results were more rapid with a mixture of equal parts of the aqueous gentian violet solution and calamine lotion.

Penicillin ointment (500 units per gramme) applied on a wick of ribbon gauze gave excellent results in some cases, but in many cases it caused an exacerbation, often severe. It was not determined whether this was due to sensitivity to penicillin or the ointment base, insufficient concentration of penicillin, or the growth of penicillin-resistant organisms.

When the condition had resolved and treatment was discontinued the patient was requested to return one week later to confirm the cure.

#### Chronic Otitis Externa

This condition was diagnosed when irritation or meatal discharge had been present for at least a month with no evidence of spontaneous cure. Many cases gave a history of acute attacks at intervals, and in some the cause of these attacks appeared to be the same as those already mentioned under the aetiology of acute otitis externa. The occurrence of intercurrent attacks of furunculosis has already been mentioned.

The severe cases varied from those of comparatively recent origin, where the meatus was filled with offensive epithelial debris and cerumen to the old-standing case with gross oedema and sub epithelial thickening of the meatal walls and pinna. The mild cases showed an absence of cerumen, or pale offensive cerumen was present. If the meatus was moist the pus was offensive and flaky, and if dry the meatal walls were covered with dry scales.

Self treatment with peroxide of hydrogen, some glycerin preparations, or unsuitable proprietary applications was found to cause an acute otitis or exacerbate one already present. Some patients stated that the condition was made worse by washing with soap and water. Patients working on grinding or cutting machines where suds (composition soda ash, 28 lb (12.7 kg), soft soap, 43 lb (19.5 kg), water, 100 gallons (455 litres)) were employed as a lubricant and cooling agent would scratch an irritating ear with the soiled hand, and some resistant cases involving the pinna were cured when a scarf was worn round the head during work. Associated seborrhoeic dermatitis of the scalp was infrequent.

**Treatment**—As in the acute form of the disease, scrupulous removal of the pus and epithelial debris was practised. Occasionally in addition the patient was instructed how to cleanse

his meatus with dry cotton wool tipped probes when daily treatment could not be given by the factory nursing staff. In the isolated case this appeared to hasten a cure.

The choice of medicament lay between those held in a watery base and those in an oily or greasy base. As a rule dry lesions of the meatus reacted best to oily preparations such as pigmentum hyd nit ung hydrarg ammon dil, Lassars paste or zinc and castor oil cream. In the atrophic type of ear the use of a preparation such as pig hyd nit was prolonged, and the applications continued at increasing intervals. Moist lesions were treated with gentian violet or aluminium acetate solution.

#### Otitis Externa with Granulations

Sessile granulation tissue arising from the meatal walls or external surface of the ear-drum occurred with the acute sub-acute and chronic forms of otitis externa. When the granulation tissue arose from the ear-drum the differential diagnosis from otitis media was made by the absence or slight degree of deafness, the appearance of the unaffected portions of the ear drum, and the absence of fresh pus from the affected area when negative pressure was applied with a Siegle's speculum. The granulation tissue could arise from any part of the tympanic membrane, but was more often seen on the membrana tensa. Multiple sites of origin were more common than solitary sites. Healing was slow but when complete a scar did not result. Several patients were seen again with a recurrent attack and the granulations then usually sprang from the areas previously affected. Concomitant herpes labialis or acute coryza did not occur in these cases.

**Treatment**—The meatus was cleansed by frequent or daily dry mopping and 50% surgical spirit was instilled. The granulations were touched with trichloroacetic acid solution at weekly intervals.

#### Results of Treatment of Otitis Externa

Table IV shows the number of patients seen, the number and percentage of recurrences and the average duration of

TABLE IV—*Otitis Externa*

	No of Patients Seen	No of Recurrences	Average Duration of Treatment in Weeks
Furunculosis	48	10 (20%)	1.2
Acute otitis externa	110	10 (9%)	1.8
Chronic	218	45 (20%)	2.8
Otitis externa with granulations	13	1 (7%)	3.5

treatment. It will be seen that furunculosis and chronic otitis externa have a high recurrence rate (20%). In 54 patients the condition was so slight that no treatment was considered necessary and 71 other patients did not complete the treatment. The remainder were cured.

It must be stressed that no deductions can be drawn about the efficacy or the duration of treatment. This part of the investigation was not planned to determine the comparative efficiency of various forms of treatment; descriptions of the methods used have been mentioned only to indicate the range of treatment. The disease has been found to cause more pain with resulting loss of working efficiency than chronic suppurative otitis media and considerable care and treatment have been necessary for its alleviation.

#### Other Conditions of Pinna and Meatus

**Otitis Externa Bullosa and Haemorrhagica**—These conditions were seen in 11 patients in all of whom the condition was unilateral. In 6 of these cases the vesicles were filled with blood. Concomitant otitis media was observed in 1 case.

**Osteoma of the External Meatus**—The condition was seen in 6 patients and in no case was the meatus obstructed or the hearing affected.

**Developmental abnormalities**—One case of complete atresia of the external meatus and maldevelopment of the pinna associated with gross perceptive deafness in that ear was seen. The function of the other ear was apparently normal. In another case an accessory auricle was present consisting of an irregular fleshy projection arising from the cheek just in front of the left tragus. The pinna, external meatus and tympanic membrane were normal and there was a mild presbycusis equal

in both ears. In neither case was there a familial association. Five examples of developmental stenosis of the meatus were encountered.

#### Acute Otitis Media

This term is limited to those cases where the history and the physical signs provided no evidence of a previous attack of otitis media. Those cases in which previous attacks had occurred will be described under recurrent chronic suppurative otitis media.

**Non suppurative Acute Otitis Media**—Pain, deafness, and in acute upper respiratory infection were present in all cases. The appearances varied from localized dilatation and redness to generalized redness and bulging of the tympanic membrane.

**Treatment**—Where the inflammatory changes in the tympanic membrane were slight and localized spirit ear drops were instilled daily to sterilize the meatus and steam inhalations were given twice daily to combat the nasopharyngeal infection. The other cases were referred to the patient's medical practitioner for treatment by chemotherapy.

**Results**—Sixteen cases were seen, all unilateral. Five patients were not seen again. The remaining 11 ears resolved, and in all except one case the hearing was restored to its previous level.

**Suppurative Acute Otitis Media**—In all the cases perforation of the tympanic membrane had already occurred. An acute upper respiratory infection was held to be the cause in 5 cases; the remainder were due to local trauma from blows on the ear or the insertion by the patient of such objects as match sticks or Kirby hair grips to allay irritation of the external meatus.

**Treatment**—Pus was removed daily by syringing, sulphamidamide powder with boric acid was insufflated and a cotton wool plug was inserted in the outer meatus. Any nasopharyngeal infection was treated with steam inhalations.

**Results**—Ten cases were seen, all unilateral. All resolved with treatment and the hearing was restored to its previous level.

#### Chronic Suppurative Otitis Media

**Definition of Terms Employed**—Consideration of the history allowed of the division of the cases into two groups according to the continuity of the otorrhoea. If this has been without break since the onset of the disease the condition may be termed 'continual,' whereas if the otorrhoea ceases and the middle ear becomes dry, only to relapse at a later date the condition may be termed 'recurrent.' Accurate placing of the cases into either group was not always possible in the absence of previous clinical examination. If the discharge temporarily diminishes so that evaporation will suffice to prevent it emerging from the entrance of the external meatus the patient may conclude that the ear is dry when such is not the case. For the purposes of classification used in this paper those cases of middle ear disease where the otorrhoea ceases for periods of less than one month were placed in the 'continual' group, and those with a dry ear for periods of more than one month were placed in the 'recurrent' group. The classification is based on the supposition that an ear subject to recurrent attacks of infection will be more likely to become dry with treatment than the ear from which the discharge has been continual. This grouping has been found of value as a simple aid for the determination of the severity of the disease and the reaction to treatment. It is realized that the classification is not a completely accurate diagnostic criterion. Certain cases placed in the 'recurrent' group will, for the reason stated above, belong to the continual group, though the opposite is unlikely to occur.

The results of treatment have been classified under the heads of 'cure,' 'quiescence' and 'failure.'

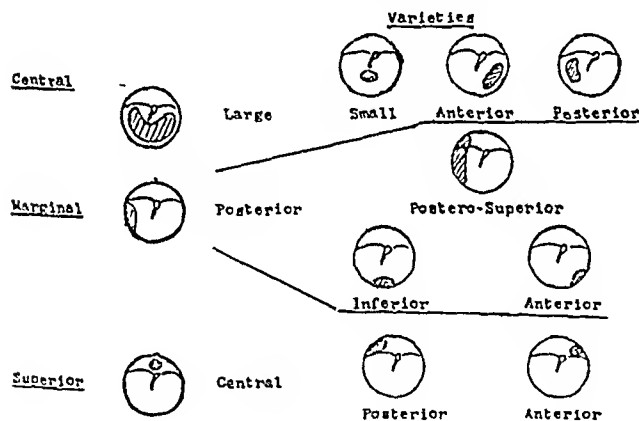

The criteria held to be necessary for a case to be regarded as cured vary according to the previous history. In the recurrent case with previous attacks of short duration the present attack was regarded as cured when observation after a minimum period of one week without treatment disclosed the middle ear to be dry on inspection and by mopping with a fine wool tipped probe through the perforation. In the other type of recurrent case where previous attacks had been few and possibly the 'present' attack had been of long duration, the same criteria were used if during treatment there

had been a steady decline in the amount and improvement in the nature of the discharge. "Continual" cases were regarded as cured when the middle ear was dry for a minimum period of two weeks without treatment. In some cases it was possible to examine the ear at intervals up to a year after cure, but, while it is desirable to do this in all cases, circumstances outside the control of this investigation have made this impossible.

It is considered that the inclusion of certain cases under the heading of "quiescent" is justified from the administrative aspects of an ear-treatment service. Cases have been placed in this group when, despite prolonged and adequate treatment and subsequent weekly or monthly observation, the middle ear only remained moist but pus did not flow through the perforation. The less severe cases merely required inspection and toilet at monthly or longer intervals. The more severe cases required frequent inspection and toilet. Without this regular treatment the infection may become more severe, with the production of pus appearing at the meatus in the form of either an acute exacerbation or a gradual recrudescence.

Treatment was regarded as failing if, after an adequate course of at least four to six months, pus was found in the external meatus within 24 or 48 hours after the last treatment. Except in 16 cases where no lessening of the discharge occurred, treatment resulted in diminution of offensive odour and the amount of the discharge, this appeared to be the reason for the persistence with which the patients attended over long periods. In this group were many cases in which the hearing was such that an increase of the deafness would be expected if surgical procedures were resorted to.

For the purposes of description the positions of a perforation will be described under certain groups. The diagrams show the relation to the principal landmarks of the ear-drum.

Alterations in the size and shape of the perforation have been observed during the course of treatment but are without prognostic significance. Migration of the perforation has been seen in a few cases but not to a degree sufficient to alter the original designation.

Double perforations fall into two varieties. In one, both perforations are in the membrana tensa, usually in front of and behind the handle of the malleus and are classified as 'central'. In the other variety one perforation is in the membrana tensa, the other in the membrana flaccida. In all the examples seen of the latter variety the superior perforation has shown the greater activity and the case has been classified as 'superior'.

**Aetiology.**—Age of onset. Table V shows the age at the onset of the first attack of otitis media where a reliable history could be obtained. It will be noticed that 44.4% of the patients

TABLE V.—Chronic Suppurative Otitis Media. Age at Onset of First Attack.

Age	0-5	6-10	11-20	21-30	31-40	41-50	51-60	Over 60	Total
No. of patients	78	28	61	49	23	9	2	1	261
Percentage of total	29.9	10.7	23.4	18.7	8.8	3.4	0.7	0.3	100

experienced their first attack in the first decade of life. Thereafter there is a steady decline with each decade. It is probable

that some patients, having no recollection of otitis media in childhood, gave a later date and have caused the incidence in later decades to be too high.

Evidence has been found in the cases treated that the removal of the factors leading to chronicity is often feasible and will result in the cessation of the otorrhoea. That chronicity may be due to one factor alone has been shown by individual cases in which the otorrhoea had been present for over six months. Thus prevention of stagnation of the discharge due to inefficient treatment allowing of its accumulation resulted in a dry ear in 77% of the successfully treated ears. The removal of cholesteatoma present in the middle ear led to a dry ear in 17% of the successfully treated ears, and of granulation tissue or polyp in 22.5% of those successfully treated. Two or more factors were commonly present in the one case, such as stagnation and granulation tissue, and it was not until both causes had been removed that a cure resulted. In certain cases circumstances led to the removal of one factor before the other, and the result justified the above conclusion. It is accepted that necrosis of bone in the middle ear cleft and infection of the mastoid antrum and air cells are factors causing chronicity, but the facilities at the disposal of this investigation did not enable corroboration of this to be obtained.

Chronic suppuration of the nasal sinuses was held to be the cause of chronicity in 8, chronic infection of the tonsils in 19 and chronic infection of the adenoids in 6 patients.

Ascending infection from the Eustachian tube was common, and an acute respiratory infection was a frequent cause in many cases of recurrent attacks of otitis media. The middle ear remained infected until the nasal and pharyngeal infection had subsided. It was noted that when the middle ear was already infected the supervention of an acute respiratory infection caused an increase in the amount of the otorrhoea in all cases with an anterior or central perforation of the ear-drum, occasionally with a postero-central perforation, and rarely with a superior or postero-superior perforation.

#### Methods of Treatment Adopted for CSOM

The elimination of infection in the nose, mouth, or pharynx causing an ascending spread via the Eustachian tube was considered to be an essential part of the treatment of chronic suppurative otitis media. The method of removal of the pus from the ear has been conditioned by the nursing facilities in the factory medical departments. It is admitted that syringing may transfer bacteria from the skin of the outer meatus into the middle ear and that mopping with a dry cotton-wool-tipped probe under direct vision through an aural speculum will reduce this mode of infection. The latter form of treatment, however, requires skilled personnel to attain thorough and painless removal of the pus. The lack of previous experience of conservative ear treatment, the changes of nurses on a duty rota, and the small numbers of patients treated have prevented the attainment of this skill. As a matter of expediency, syringing has therefore been adopted in most cases. Exceptions were made in some of the cases with associated otitis externa, where it was thought that the introduction of water would exacerbate or delay the resolution of the meatal condition, and those cases where syringing even with water carefully adjusted to the body temperature caused objectionable vertigo. In these latter cases the progress of the middle-ear condition has been slower. Deficiencies in the adopted method of daily treatment have to some extent been made up by a thorough cleansing of the meatus and middle ear under direct vision by the otologist at weekly intervals.

The choice of medicament used after cleansing the middle ear has been determined by the requirements of the case and the previous experience of the otologist. No new preparations have been employed. The ones chosen have been employed because the results from their use are already known and not because it is considered that other medicaments are of less value.

Where there was profuse discharge, epithelial debris, granulation tissue or cholesteatoma, drops of surgical spirit 50% in water were employed with the aim of effecting greater penetration of the exudate. It was considered that a dry powder would either be rapidly washed out by the discharge or remain on the surface of the debris or granulations. Where the discharge

was moderate or scanty, and particularly in those cases with a large central perforation, insufflations of powder were chosen. Equal parts of sulphanimide powder and boric acid gave satisfactory results except in those cases, mentioned in a previous section, where a local reaction of the meatal skin occurred. In such cases a change to spirit drops or iodine and boric powder was generally sufficient to cure the meatal condition.

The frequency of treatment of the individual case was mainly determined by the amount of the discharge. Daily treatment was given when pus was present in the meatus, and was discontinued when the middle ear kept dry for at least twenty-four hours without attention. In certain cases where no offensive odour was present daily treatment was discontinued when it had been carried out for at least two months and the discharge had become so scanty that on two consecutive weekly examinations the pus was visible only on a wool-tipped probe after mopping through the perforation. The patient was then seen at weekly intervals, and if the quantity of the discharge increased a return was made to daily treatment. If all was well the ear was regarded as quiescent.

Quiescent ears were examined at weekly, monthly, or longer intervals according to the amount of pus present at each visit and the length of time since daily treatment had been discontinued. Any epithelial debris, wax or bead of pus in the middle ear was removed, and if necessary the middle ear was flushed out with warm spirit using an attic syringe. The ear was then dried with wool-tipped probes and lightly dusted with powder.

Granulation tissue and polypi were not treated until the ear had had one or two weeks' daily treatment. It was considered that an effort should first be made to reduce the amount of infection and allow for the shrinkage of inflamed mucous membrane. Sessile granulations were touched with a concentrated solution of trichloroacetic acid on a fine wool-tipped probe, or, when a more penetrating action was desired, with a bead of chromic acid fused on to the tip of a fine straight or bent metal probe. Larger granulations were removed with cup forceps and the stump treated with one of the above mentioned escharotics. Polypi were removed with an aural cutting snare or cup forceps after preliminary analgesia induced by 20% cocaine solution applied sparingly on pledgets of cotton wool packed round the pedicle. Care was taken in cases where granulations or polypi arose from the inner wall of the middle ear or from the upper part of the posterior wall of the middle ear in proximity to the facial nerve.

Cholesteatoma in the middle ear was removed by the use of an attic syringe, bent probes, or forceps, after preliminary shrinking with spirit.

The reintroduction of infection via the external auditory meatus was diminished by stressing the importance of this route to the patient.

### Results of Treatment of Chronic Suppurative Otitis Media

In presenting the results it has been necessary to allow for the high proportion of patients who did not continue treatment until the effect could be assessed. Out of 274 patients seen with chronic suppurative otitis media 39 attended for less than one week's treatment and 58 cases defaulted after longer periods of treatment. Six patients were still under treatment when the results were assessed.

Cases defaulting after less than one week's treatment can be disregarded, as can those still under treatment. It is not possible to ignore the third group. The incompletely treated group of cases having at least one week's treatment will consist of those patients who, as confirmed occasionally by subsequent examinations, rightly concluded that the ear was dry and did not return for final examination, and those patients with an ear condition not amenable to even a prolonged course of conservative treatment. To assess the results solely on these cases adequately treated would leave out of account an unknown quantity of considerable size. The figures presented (see Table VI) therefore represent the minima or maxima as the case may be.

TABLE VI—*Chronic Suppurative Otitis Media Results of Treatment*

	No Seen	No Where Treatment Completed	No Where Treatment Completed + No Partially Treated	No Cured	% of Fully Treated Cases Cured	% of All Treated Cases Cured
Patients with unilateral disease	232	161	199	135	83.8	67.8
Patients with bilateral disease	42	26	36	14	53.8	38.8
Number of ears	316	213	271	173	81.2	63.8

It will be seen that out of 232 patients with unilateral disease 199 received one or more weeks' treatment and 161 had a full course of treatment. At its termination 135 were dry. This gives an immediate cure rate of 67.8% for patients receiving one or more weeks' treatment, or 83.8% for patients receiving adequate treatment. As already explained, the true cure rate will lie somewhere between these two percentages.

Of 42 patients with bilateral ear disease 36 received one or more weeks' treatment and 26 a full course of treatment. In 14 patients both ears were dry at the end of treatment, giving an immediate cure rate of between 38.8% and 53.8%. Of a further 10 patients in whom one ear became dry as a result of treatment the other ear was rendered quiescent in 6 and the remaining 4 ceased attending.

The average duration of treatment for the cured cases was 5.2 weeks (limits, 1 week to 7 months).

Table VII shows the duration of the otorrhoea in 276 ears. The 'recurrent' ears are shown separately from the 'continual' ears. It will be seen that 84% of the 'recurrent' ears

TABLE VII—*Chronic Suppurative Otitis Media Duration of Otorrhoea and Results of Treatment*

	Less than 6 Months		6 Months to 1 Year		1 to 5 Years		Over 5 Years		Total
	Rec	Cont	Rec	Cont	Rec	Cont	Rec	Cont	
No of ears	101	20	6	6	12	26	2	103	
Total	121 (44%)		12 (4%)		38 (14%)		105 (38%)		276 (100%)

had been discharging for less than six months and 66% of the 'continual' ears for more than five years. More than half of these ears had been discharging for more than one year.

In Table VIII 247 ears are classified according to the intermittency or otherwise of the discharge. Excluded from the table are 25 'continual' ears in which the duration of the discharge could not be determined.

TABLE VIII—*Chronic Suppurative Otitis Media Results of Treatment in 'Recurrent' and 'Continual' Cases*

Duration of Discharge	Recurrent Ears	Continual Ears				Total
		Less than 6 Months	6 Months to 1 Yr	1 to 5 Years	Over 5 Years	
Ears treated	112	17	5	23	90	135
Ears cured	92 (83%)	11 (65%)	4 (80%)	10 (43%)	43 (48%)	68 (50%)
Ears quiescent	5 (4.5%)	1 (5%)	0	1 (4.3%)	10 (11%)	12 (8.9%)
Ears failed	0	1	1	6	8	16 (11.8%)

Despite the high proportion of patients not completing treatment 83% of the recurrent ears were treated with success in an average period of four weeks while only 50% of the continual ears responded in an average period of 6.7 weeks.

There was no relation between the duration of the disease and the length of treatment necessary to effect a cure.

The recurrent group does not contain any failures and the ears rendered quiescent are only half as frequent as those in the continual group. In the latter group it would appear that otorrhoea lasting longer than one year carries a worse prognosis for successful conservative treatment.

Marginal and superior perforations were found to occur most frequently in the 'continual' cases and were rare in the 'recurrent' cases.

A total of 90 ears were seen in which granulation tissue or a polypus arising from the middle ear or tympanic membrane was present. Of these 55 showed granulation tissue and 35 showed polypi. The total figure represents 28.8% of all ears with chronic suppurative otitis media examined.

Of the 'recurrent' ears treated, 19.3% had granulation tissue, compared with 35.5% of the 'continual' ears. As a result of treatment it was found that there was a slight worsening of the prognosis when granulation tissue was present in the ear, but the better prognosis of the 'recurrent' over the 'continual' case was again observed. If the granulation tissue arose from the tympanic membrane or external auditory meatal walls only slight reduction of the cure rate resulted, but where the site of origin was from the tympanic ring or the middle ear the prognosis was much worse.

Six cases of cholesteatoma of the middle ear were seen. In three patients a dry ear was obtained.

#### Relation between Hearing, Clinical Condition, and Effects of Treatment

Long duration of the disease since the first onset was not found to be necessarily associated with poor hearing, although severe deafness was relatively more common with cases of longer than five years' duration than with those of less than one year's duration.

The site of the perforation in the tympanic membrane was not related to the degree of hearing loss. Similarly, the possession of good hearing at the outset of treatment did not necessarily imply a good response to treatment nor did the reverse hold true.

Table IX, in graphic form, shows the change in hearing as a result of treatment. The values marked along the abscissa

TABLE IX—Chronic Suppurative Otitis Media. Improvement in Hearing as a Result of Treatment

record the change in hearing according to the number of hearing groups. Thus if an ear when first seen could hear a forced whisper at a distance of three feet and at the end of treatment a forced whisper could be heard at a distance of 18 feet, the improvement in hearing is recorded as two groups. When the hearing improved only from, say, an ability to hear a forced whisper at a distance of three feet before treatment to five feet after treatment, the improvement is recorded as half a group. Ears showing deterioration of hearing are recorded on the left of the ordinate. The resulting curves show that in many ears the hearing is unchanged as a result of treatment, but that the

hearing in the remainder was more often improved than worsened. Further the upper curve shows that even when treatment did not result in a dry ear, or was discontinued before completion, some improvement in hearing resulted, although the left-hand half of the curve shows that deterioration was more common.

#### Recurrence of Otorrhoea After Successful Treatment

To obtain an estimate of the proportion of cases in which a relapse of infection occurred after treatment a postal questionnaire was sent to the patient after an interval varying from six to eighteen months. Replies were received from 65% of the total number questioned, and of these 27 attended for examination by the otologist. In addition 28 patients were examined at least six months after their last treatment.

Thus out of 235 patients 53 were examined by the otologist and 63 sent a report on their condition six to eighteen months after the termination of treatment.

The results of this follow-up are shown in Table X. The term 'immediate' cure is applied when the ear is dry at the end of treatment and 'prolonged' cure when the ear has remained dry for at least six months after the end of treatment.

TABLE X—Chronic Suppurative Otitis Media. Reinfection after Treatment

	Examined by Otologist		Report from Patients	
	Unilat.	Bilat.	Unilat.	Bilat.
Immediate cure	37	3	42	2
Prolonged cure	20 (54%)	1 (33%)	29 (69%)	—
Relapse	17 (46%)	2	13 (31%)	—
Immediate quiescence	6	1	1	—
Prolonged cure	2	—	—	—
Still quiescent	4	1	1	—
Failure (In statu quo)	1	—	1	—
Defaulted before treatment completed	5	—	15	2
Prolonged cure	1	—	4	—
In statu quo	4	—	11	2

Of the patients examined by the otologist it will be seen that of 37 'immediate' cures in unilateral cases 54% were 'prolonged' and of 3 bilateral 'immediate' cures in both ears only one was 'prolonged'. Of 6 unilateral and 1 bilateral cases 'immediately' quiescent 2 unilateral cases subsequently became dry. Four unilateral and the one bilateral case were still in the same condition six or more months later.

Similarly, of the cases reported by the patients, 69% of the unilateral and both of the bilateral cases were said to be 'prolonged' cures.

Examinations of patients suffering from chronic suppurative otitis media occasionally showed abnormal conditions in the opposite ear. Table XI summarizes the findings and shows the percentage incidence of the total number of patients examined (274). Of these patients 50.3% had evidence of past or present suppuration in the opposite ear.

TABLE XI—Chronic Suppurative Otitis Media. Conditions Present in Opposite Ear

	No.	Percentage
Chronic suppurative otitis media (e.g. bilateral disease)	42	15.3
Healed otitis media	80	29.2
Healed cortical mastoidectomy	6	2.2
Healed radical mastoidectomy	10	3.6
Total	138	50.3% of 274 patients

Associated otitis externa was found in the affected ear in 17 cases of chronic suppurative otitis media.

In the whole series of cases a positive fistula sign was discovered in 2 cases, vertigo from labyrinthine irritation in 2 cases, and suspected intracranial complication in 2 cases.

Cases requiring surgical treatment may be considered under two heads. Those of relative urgency were two in number. Both exhibited a positive fistula sign. The other cases belong to the group in which conservative treatment failed and where surgical treatment would be one of convenience. In more than

half of these the hearing was of sufficient acuity to suggest the choice of an operation designed to preserve the residual hearing rather than the full radical operation

#### Healed Otitis Media

The ears grouped under the term 'healed' otitis media are those in which the ear drum shows scars or perforations with no evidence of active infection such as pus, redness, or dilatation of the blood vessels. Those ears which are subject to recurrent attacks of inflammation and happen to be examined during a quiet phase will be included in this group. If the ear was initially examined during the quiet phase and was later seen with a recurrence of inflammation, it has been placed in the group of recurrent chronic suppurative otitis media. Cases in which a mastoid operation had been performed are dealt with under a separate heading.

A total of 249 patients have been observed of which 96 were right-sided, 78 left-sided, and 75 bilateral. In 32 cases there was a history of recurrent attacks of otorrhoea and of an attack within the previous five years.

Table XII shows the age at which the first attack occurred in those cases in which a history could be obtained. It will be seen that 57% of the patients stated that the initial attack occurred in the first decade of life.

TABLE XII—Healed Otitis Media Age at Onset

Age	0-5	6-10	11-20	21-30	31-40	41-50	51-60	Over 60	Total
No. of patients	57	29	26	19	16	4	1	1	153
Percentage distrib	37.3	19.0	17.0	12.5	10.5	2.5	0.6	0.6	100/

When the initial attack occurred more than 20 years previously 38% of the ears had a severe hearing loss (whisper heard at a distance of less than 5 feet) and only 51% had moderate or good hearing (whisper heard at more than 10 feet distance). By contrast, when the initial attack occurred within the previous 5 years only 10% had a severe hearing loss and 83% had moderate or good hearing. This indicates that progressive deafness will result from a healed infection.

#### Healed Cortical Mastoidectomy

A total of 28 ears have been seen, in which the disease was right-sided in 12, left-sided in 12, and bilateral in two. The age at the time of operation is shown in Table XIII.

TABLE XIII—Healed Cortical Mastoidectomy Age at Operation

Age	0-5	6-10	11-20	21-30
Number of ears	3	10	13	2

Out of these 28 ears, 14 were found to have infection of the middle ear. In two the pus was coming from the attic region. One case of facial palsy due to the operation was observed. Of 10 ears receiving adequate conservative treatment on the lines detailed under chronic suppurative otitis media, nine responded with cessation of the discharge, the average duration of treatment being 7.1 weeks. The other four ears with infection of the middle ear ceased attending for treatment before the result could be ascertained.

Table XIV shows the hearing recorded according to the state of the middle ear and the condition of the tympanic membrane. The presence or absence of infection in the middle ear does not appear to have any relation to the hearing in the small number of cases seen.

TABLE XIV—Healed Cortical Mastoidectomy Hearing Loss

	Middle Ear Dry Drum Intact	Middle Ear Infected
Forced whisper heard 0-2 ft	4	3
3-5 ft	1	1
6-10 ft	2	2
11-20 ft	2	6
over 20 ft	6	2

#### Healed Radical Mastoidectomy

A total of 49 ears were seen in five cases bilateral. Among these cases were five operated on by the transmastoid route and in six a modified operation had been performed with

preservation of the tympanic annulus. In 24 ears the cavity was infected from the Eustachian tube. Four cases of facial palsy due to the operation were observed.

Table XV shows the duration of otorrhoea before the operation had been performed and the degree of deafness at the time of examination. Nearly two thirds of the ears had had the

TABLE XV—Healed Radical Mastoidectomy Hearing Loss and Duration of Otorrhoea before Operation

	Hearing Loss	Duration of Otorrhoea Before Operation				
		0-5	6-10	11-20	Over 20 Years	Duration not known
No. of ears	49	8 (35/)	7 (29/)	5 (22/)	3 (13/)	26
Severe perceptive deafness	8					
Forced whisper heard 0-2 ft	24					
Forced whisper heard 3-5 ft	6					
Forced whisper heard 6-10 ft	2					
Forced whisper heard 11-20 ft	9					

operation within 10 years of the first onset of the otorrhoea. Despite this 77% of the ears were severely deafened (forced whisper heard at five feet distance or less) indicating the serious effect on hearing of severe ear disease and the failure of the radical mastoidectomy operation to restore a useful degree of hearing.

#### Eustachian Obstruction

In 65 patients 96 ears were seen of which 31 cases were bilateral and 34 unilateral. In 63 ears the condition had been present for less than two months, in the remainder the condition had been present for more than two months. In 33 ears the onset was associated with an acute upper respiratory infection. In two bilateral cases the middle ear of one side contained serous fluid, as shown by a fluid level and severe deafness. Both cases resolved with treatment.

Of these ears 41 were treated by inflation with Politzer's bag or a catheter, and all except five of the patients stated at its conclusion that the hearing had been restored to the previous level. Corroboration of their statements was not possible in all cases, as associated healed otitis media or perceptive deafness was present in some.

#### Clinical Otosclerosis

The ultimate diagnosis of otosclerosis depends on the demonstration by histological methods of the specific pathological lesion in the labyrinthine capsule. It is known that other conditions may give rise to clinical findings closely resembling true otosclerosis. In the absence of an exact dividing line acceptable to all shades of otological opinion the term 'otosclerosis' has in this work been qualified by the prefix 'clinical'. Furthermore, it is necessary to mention the principles which have been adopted in diagnosis.

The deafness is bilateral, but may be more pronounced in one ear. Its onset must be between the ages of puberty and 30 and the course slowly progressive. The upper age limit has not been exactly adhered to if there appeared to be a reasonable doubt about the age at onset. Several patients while denying any hearing loss before the age of 30 admitted that their hearing was then not so acute as other people's. In conformity with the view that the condition is inherited but with a recessive characteristic a history of the disease in blood relations is not held to be essential but its presence adds confirmation. A history of otitis media or thickening, scarring, or perforation of the tympanic membrane has excluded the case from the diagnosis of otosclerosis though there is no reason why the two conditions should not exist in the same individual. The absence of pathognomonic changes in the tympanic membrane has as with the family history been regarded as confirmatory but not essential. Tuning fork tests show the deafness to be of the conductive type but concomitant perceptive deafness is counted as additional evidence. Finally no more than a slight and short-lived improvement in the hearing results from instrumental Eustachian inflation.

A total of 26 cases of clinical otosclerosis have been examined. A family history was obtained in 10 (38%). The average

age at which the deafness was first noticed was 22.5 years. In 14 (54%) a demonstrable degree of perceptive deafness was found with tuning-fork tests. Table XVI shows the hearing in the ears.

TABLE XVI—*Clinical Otosclerosis Results of Hearing Tests*

	Better Ear	Worse Ear
Forced whisper heard 0-2 ft	22	24
1-5 ft	4	2
over 5 ft	—	—

#### Conductive and Mixed (Conductive and Perceptive) Deafness of Unknown Aetiology

The cases placed in this category gave no history of previous inflammatory ear disease and the tympanic membranes were normal. No improvement resulted from instrumental Eustachian inflation. They have not been considered under the section on clinical otosclerosis because the age at which the deafness was first noticed was before puberty or well after the age of 30, or the onset of the deafness was of too recent an origin to judge whether spontaneous improvement would occur. It is possible that many of these cases are due to inflammatory adhesive processes in the middle-ear cleft, but no positive evidence for this could be found. A total of 7 cases of conductive and 13 cases of mixed deafness were encountered.

#### Perceptive Deafness

The cases considered in this section include those with perceptive loss of hearing as the sole cause of deafness and those in which, in addition the deafness was partly due to lesions in the conductive mechanism of known aetiology. The exceptions are cases due to clinical otosclerosis and mixed deafness of unknown aetiology. A total of 117 cases were seen, and Table XVII shows the associated lesions or the conditions of possible aetiological significance present at the onset of the deafness.

TABLE XVII—*Perceptive Deafness Associated Lesions or Conditions Present at Onset*

Chronic suppurative otitis media	6
Healed otitis media	32
Healed cortical mastoidectomy	1
Healed radical mastoidectomy	6
Industrial noise	8
Artillery and other forms of explosives	22
Toxic auditory neuritis	2
Meningitis	1
Arteriosclerosis	2
Concussion or fracture of base of skull	7
Post-influenzal	2
Post-operative	2
Pre-parturition	1
Congenital syphilis	1

In 57 patients no cause for the deafness was discovered, and the age of onset of this latter group of cases is shown in Table XVIII.

TABLE XVIII—*Perceptive Deafness Age at Onset of Cases with Unknown Aetiology*

	0-10	11-20	21-30	31-40	41-50	51-60	Over 60	Total
No. of patients	2	3	4	4	19	15	10	57
Percentage	3.5	5.3	7.0	7.0	33.3	26.3	17.7	—

It will be noticed that there is a sudden rise in the incidence during the fifth decade of life. The number of fresh cases occurring during the next two decades tends to fall.

#### Other Conditions of the Ear not already Classified

A little comment is called for on these cases which are shown in Table XIX. The cases of Meniere's disease were confirmed by abnormal responses to caloric tests.

TABLE XIX—*Other Ear Conditions not already Classified*

Meniere's disease	7
Acoustic neuroma	11
Chronic otitis media with effusion	6
Chronic otitis media with granulation	3
Chronic otitis media with ossification	1

#### Conditions of Nose and Throat

The cases mentioned in Table XX occurred in patients who consulted the industrial medical officer in preference to their own medical practitioner or local hospital. In many

instances the symptoms were considered by the patient to have been caused by his work. In most cases the patient had recently come to live in the district and was not familiar with the local non-industrial medical services.

TABLE XX—*Conditions of Nose and Throat*

Nose	14
Vasomotor rhinitis	8
Chronic rhinitis	3
Vestibulitis	1
Epistaxis	3
Deviation of nasal septum	13
Nasal polypus	8
Nasal sinusitis	5
Throat	2
Acute pharyngitis and tonsillitis	9
Chronic pharyngitis	5
Chronic tonsillitis	1
Chronic catarrhal laryngitis	1
Fibroma of larynx	1
Tuberculous laryngitis	1
Nasopharyngeal carcinoma	1
Post-cricoid carcinoma	1
Unclassified	3

The case of tuberculous laryngitis occurred in a woman aged 22 whose chest was said to have been radiologically normal three months previously. There is no doubt that this woman was sent away for proper treatment at an earlier date than she would have been if a visiting specialist had not been readily accessible at the factory.

Table XXI lists the examinations conducted for suspected disease of the ear, nose, or throat where nothing abnormal was discovered. It may be noted that, with the exception of the

TABLE XXI—*Suspected Disease of Ear, Nose or Throat Nothing Abnormal Found*

Otalgia	19
Symptomatic deafness	20
Symptomatic otorrhoea	10
Suspected ear, nose or throat disease acting as a focus of sepsis	9
Suspected retained pharyngeal or oesophageal foreign body	4

cases examined for suspected focal sepsis these patients would rarely be seen in hospital practice, although they are only too familiar to the general practitioner.

A further 24 patients were found on examination to have miscellaneous conditions of other parts of the head or neck.

#### General Observations on the Clinical Results

The results of ear disease in the majority of cases are not dangerous to life but will cause varying degrees of disability. In severe cases a fatal termination or a temporary or permanent loss of wage-earning capacity may ensue. In the less severe cases there will be an interference with the general well-being and activities of the individual. The loss of efficiency resulting from pain or deafness will depend on the severity and duration of the symptoms, and to some extent on the type of work in which the sufferer is engaged. It will be of value, therefore, to examine the clinical material presented here from this aspect.

Out of the total of 274 individuals found to have chronic suppurative otitis media only two were suffering from a form of the disease in which surgical treatment was considered urgent and in which the risks of neglect would endanger life. In a further 16 individuals conservative treatment had failed and a surgical operation was necessary as a matter of convenience to prevent development of dangerous complications. Thus surgery, immediate or delayed, was necessary in only 9% of the total of 187 receiving treatment.

The major cause of loss of working efficiency was pain. The degree of pain was greatest and of the longest duration with inflammatory conditions of the pinna and external auditory meatus. Infection of the middle ear rarely caused pain, and when it did it was of short duration and not usually of great severity. The frequency of otitis externa and the duration of the treatment made this condition of major importance in the organization of the factory ear-treatment service. Although the permanent effects did not give rise to the same disability as those following otitis

media, the liability to recurrence of the attacks caused in the aggregate a considerable degree of loss of efficiency

The effect of deafness on the daily life of the sufferer was noticeable in several ways. Where there had been a sudden diminution of hearing, as from an occluding plug of cerumen, acute otitis media, or an increase in the rate of progress of a progressive deafness, the patient was continually conscious of this disability, and this preoccupation caused interference with the capacity for work. On the other hand, a progressive deafness increasing at a slow, even rate was better tolerated and its severity was often not fully appreciated. Psychological adaptation to deafness was rarely judged to be complete. In the essentially communal nature of work in the factory the sufferer felt the gulf dividing him from his fellows, and this affected the contentment of his outlook on life. The direct effect of deafness on the efficiency of his work varied with his job. In the majority of cases good hearing was not essential. The general level of factory noise may often be such that conversation can be carried on only with a raised voice. If the threshold of hearing of the deafness is less than the factory noise no disability will result. It is only with certain processes carried out in quiet workrooms that good hearing may be an advantage, but it is seldom a necessity. For supervisors or clerical workers, however, the possession of fair hearing is usually important, and a deaf worker would thus find his chances of promotion curtailed. A few cases of intolerance to excessive noise have been observed, and, although this may occasionally have been a psychological "escape" reaction from monotonous work, it necessitated the individual being moved to another job in quiet surroundings. There his lack of experience may have rendered him less efficient at the work.

Working efficiency can be affected by the home life and activities outside the factory. A sense of physical inferiority induced by the deafness may exist, and even if the disability is only apparent in social intercourse the mental stress so caused may affect the relations with friends. Hence, while pain can cause a marked but short-lived loss of working power, incurable deafness, although less crippling in any one individual, may, because of its much greater incidence, be an equally important cause of loss of efficiency in the working population.

The deafness resulting from the various types of disease has already been mentioned under the appropriate sections. Out of 393 cases of severe deafness (forced whisper heard at less than 5 feet distance) due to all types of disease, 49.3%, or nearly half, were due to active or healed otitis media. Cases of otitis media associated with perceptive deafness (19%) are not included in this group.

The correct management of otitis media in the early stages, before the onset of incurable deafness, is therefore of importance. As the onset most often occurs in childhood (Tables V and XII) general-practitioner and school-treatment services are responsible for the treatment. That these services are inadequate is shown by the survey conducted among factory workers, where 33% were found to be suffering from chronic suppurative otitis media.

It has been shown in Table VI that treatment carried out in a factory medical department will result in a dry ear in 67% to 83% of the patients with unilateral otitis media and 38% to 53% of those with bilateral otitis media (both ears dry). From 5% to 6% of patients with unilateral ear disease will obtain a quiescent ear with such treatment. (Precise figures for the cure rates cannot be given, for the reasons stated previously.) Examination at a later date will show that more than half of the ears initially dry after treatment will relapse (see Table X), although a further course of treatment will be successful

in most cases. The ears rendered quiescent by treatment stand a good chance of remaining in this state with an occasional toilet, and some may eventually become dry.

If, therefore, 100 patients with unilateral chronic suppurative otitis media are given a full course of conservative treatment in a factory medical department it can be surmised from the results obtained in this investigation that 38 will have a dry ear for at least six months, 45 will have a dry ear at the termination of treatment but will relapse in under six months (although standing a good chance of cure with subsequent treatment), 6 will be rendered quiescent and 11 will need a surgical operation.

It is thus apparent that conservative treatment will result in cessation of the infection in a high proportion of cases, but the liability of the treated ear to reinfection indicates the deficiencies in this form of treatment and the poor prospect of obtaining a lifelong cure. The conservative treatment of relapses as they occur has the advantage of retaining a greater degree of hearing than treatment by a surgical operation. But even when the latter method is employed occasional treatment will subsequently be necessary.

### The Future Expansion of Factory Otological Treatment

The results of treatment obtained in the factory medical department are not as successful as those carried out under ideal conditions, but they compare favourably with those obtained in the average hospital otological out-patient department. The present investigation has been of short duration and therefore temporary. It can reasonably be expected that if a permanent service were to be set up the larger numbers dealt with and the greater dexterity of the nursing staff would improve the results of treatment. For cases requiring daily treatment, interruption at week-ends and at public holidays delays or prevents healing and is a drawback to any scheme of factory treatment that may be considered. But for most cases factory treatment is adequate and has the overriding advantage of ready accessibility to the sufferer.

The present overloading of hospital facilities would be eased by a factory ear-treatment service which by a dissemination of otological knowledge would act as a screen for the less serious cases and by prevention reduce the incidence of serious complications.

With the present shortage of trained otologists it is essential that the fullest use should be made of their time. It is necessary, therefore, that factory clinics should be large enough to justify the time spent by the otologist in travelling to the factory. From experience gained in the present investigation it is probable that a unit employing 5,000 persons would provide enough cases to justify the organization of a treatment service, and that a unit of 15,000 persons would require the services of an otologist for three hours once a week. Daily treatments arising in larger units would take a nurse from one to two hours each day to perform. Any permanent scheme could be satisfactorily conducted by a medical practitioner sufficiently skilled in otology to reach "registrar" status, or by one who has had the equivalent of two years' whole time experience in otolaryngology. It would be desirable for him to be based on or have a close liaison with the ear department of the local hospital (such as a clinical assistantship), so that unusual cases could be referred there for fuller investigation and the opinion of the consultant.

Single factories employing large numbers of individuals are unusual in Great Britain, but industrial medical officers are of the opinion that it would be feasible to organize a treatment service based on a small factory which could treat the employees of other factories in the near district. Each

manufacturing area would present its own problems of organization, but in a congested area such as Birmingham a considerable proportion of the factory population could be included.

The prevention of deafness is an important factor in the nation's health. An ear-treatment service based on the factory is a feasible method, causing the minimum interference with the productive capacity, of arranging treatment for a part of that section of the community of great importance to the economic wealth of the country.

### Summary

Chronic ear diseases, in particular chronic suppurative otitis media, are potent causes of inefficiency, invalidism, or early death. Experience during the 1939-45 war showed that disease of the ear was a serious cause of wastage of man-power. The high incidence of this disease is largely due to inefficient treatment resulting from the absence of an ear-treatment service adapted to the economic needs of the population.

Before and during the last war many industrial concerns set up medical departments to safeguard the health of the employees and to treat minor injuries sustained at work. This report gives an account of otological work carried out in seven factory medical departments over a period of eighteen months, with the object of ascertaining (a) the incidence of suppurative otitis media in factory workers and (b) the results of treatment of ear disease in the factory medical department.

To determine the incidence of ear disease in the factory population 1 902 employees, selected at random, were examined. Of these, 3.3% were found to be suffering from suppuration in the middle ear and 17.8% had active or healed middle ear disease.

A total of 1 711 patients complaining of ear, nose or throat symptoms were examined at clinics set up in the factory medical department. 389 were found to be suffering from disease of the pinna and external auditory meatus and 274 from chronic suppurative otitis media. The effect of otitis media in the causation of deafness and the results of treatment are considered in detail.

From the results of treatment it is deduced that, if 100 patients with unilateral chronic suppurative otitis media receive a full course of conservative treatment in a factory medical department for an average period of 52 weeks 38 will have a dry ear at the end of treatment and will keep dry for at least six months after its termination 45 will have a dry ear at the end of treatment but will relapse in less than six months (although standing a good chance of cure with subsequent treatment), 6 will be rendered quiescent and 11 will need a surgical operation. The results show that conservative treatment will result in cessation of infection in a high proportion of cases, but the prospects of obtaining a lifelong cure are poor. It is concluded that a surgical operation does not offer an effective alternative method of treatment in all cases.

The effects of deafness and pain on the working capacity of the factory employees are discussed. It was found that in manual workers productive efficiency was affected more by pain than by deafness but that the latter may be a handicap to promotion.

The future expansion of otological treatment in factory medical departments on a permanent basis is discussed and it is concluded that such a scheme is feasible, is adapted to the needs of the working population and would reduce the present overloading of the hospital services.

I am indebted to Mr Terence Cawthorne for his advice through the intermediary of Dr Donald Stewart for advice on industrial medicine and to Mr C. S. Hall for his help in the preparation of this paper. The following industrial concerns have assisted in the organization of an ear clinic: Dr J. G. B. Brown, Dr E. H. Capel, Dr J. G. Lewis, Dr D. W. McEwen, Dr D. W. A. McClelland, Dr N. G. W. and Dr A. W. for their help in the organization of an ear clinic. The directors of the following organizations have assisted in the organization of an ear clinic: Messrs. J. G. B. Brown & Co., Ltd., Birmingham; Messrs. J. G. B. Brown & Co., Ltd., Glasgow; Messrs. J. G. B. Brown & Co., Ltd., London; Messrs. J. G. B. Brown & Co., Ltd., Manchester; Messrs. J. G. B. Brown & Co., Ltd., Newcastle; Messrs. J. G. B. Brown & Co., Ltd., Nottingham; Messrs. J. G. B. Brown & Co., Ltd., Oxford; Messrs. J. G. B. Brown & Co., Ltd., Plymouth; Messrs. J. G. B. Brown & Co., Ltd., Reading; Messrs. J. G. B. Brown & Co., Ltd., Southampton; Messrs. J. G. B. Brown & Co., Ltd., Swansea; Messrs. J. G. B. Brown & Co., Ltd., Tyneside; Messrs. J. G. B. Brown & Co., Ltd., Wakefield; Messrs. J. G. B. Brown & Co., Ltd., Wigan; Messrs. J. G. B. Brown & Co., Ltd., Wolverhampton; Messrs. J. G. B. Brown & Co., Ltd., York.

## VITAMIN D IN TREATMENT OF BOECK'S SARCOIDOSIS

BY

R. F. ROBERTSON, M.B., M.R.C.P.E.

Clinical Tutor in Medicine, Edinburgh Royal Infirmary

Besnier-Boeck-Schaumann's disease, commonly known as Boeck's sarcoidosis, is now recognized as a diffuse reticulo-endotheliosis with the formation of a folliculoid tissue affecting particularly the lymphoid and haemopoietic tissues. The organs most commonly involved are the lymph nodes, spleen, lung, bone marrow, liver, eyes, and, in 50% of cases, the skin.

The skin lesions, when present, tend to cause considerable disfigurement, and hence from the patient's point of view constitute the main problem of the disease, which in other respects tends to be a benign condition without pain and systemic upset, and which progresses very slowly over a number of years. The skin lesions are of two types:

(1) A symmetrical granulomatous condition affecting chiefly the nose, cheeks, ears, and fingers, described by Besnier in 1889 under the name *lupus pernio*. (2) Multiple granulomatous swellings of varying size affecting chiefly the face and upper limbs and having a translucent appearance. To these lesions Boeck in 1897 gave the name of cutaneous sarcoids.

It is clear that the skin lesions closely resemble tuberculous lupus vulgaris. Indeed, without a skin biopsy it is often difficult or impossible to separate the two conditions.

The resemblance to tuberculosis is not confined to the skin lesions, and in recent years many writers have speculated on the possibility of sarcoidosis and tuberculosis being variants of the same disease. The following points provide good reason for such speculation: (1) The basic pathological lesion in sarcoidosis, the sarcoid follicle, consists of endothelioid cells and a zone of lymphocytes just as in the tubercle follicle. There is, however, no caseation, and the presence of tubercle bacilli cannot be demonstrated. (2) The distribution of the disease process in sarcoidosis—i.e., in the reticulo-endothelial system—is essentially the same as in tuberculosis. (3) The development of active tuberculosis is the commonest cause of death in sarcoidosis, but whether this is *post hoc* or *propter hoc* it is not possible to say.

The position has been adequately summarized by Cameron and Dawson (1946), who state that "while there is much against the idea of a tuberculous basis, notably the frequent absence of a positive Mantoux reaction, there are sufficient resemblances, clinical, radiological, and histological, to suggest a probable causal relationship." It may be that sarcoidosis is a low-grade tuberculosis of non-caseating type.

In view of the recent successful treatment of lupus vulgaris with calciferol it seemed possible that the skin lesions in sarcoidosis might react favourably to similar treatment and thus alleviate considerable aesthetic embarrassment in patients so afflicted. Care, however, was required in selecting suitable cases, since spontaneous improvement is a common phenomenon in sarcoidosis and this might be erroneously attributed to the administration of calciferol. Eventually one case was selected in which the lesions had been slowly progressing for a period of nine years and in which spontaneous improvement was not expected.

### Report of Case

The patient, a single woman, came to the Royal Infirmary, Edinburgh for the first time as an out-patient in 1938, when she was aged 43. Her past history was negative apart from a tendency to bronchitis. At that time she had a well-marked lupus pernio causing an erythematous induration of the nose,

cheeks the forehead above the bridge of the nose and a small area under the chin. There was considerable disfigurement. The process had started six years previously with nasal obstruction and discharge and a red patch on the left side of the nose which had gradually extended.

The "cutaneous sarcoid" element was also present in the form of raised indurated areas on the dorsal aspects of both arms above the wrists. In addition the fingers were markedly swollen and distorted and purple in colour, with breaking down of the nails of the most affected fingers. The toes showed similar but less severe changes. The rest of the skin surface was normal.

There was no clinical evidence of the other common manifestations of sarcoidosis such as enlarged spleen, enlarged lymph glands, and uveoparotitis, but skiagrams of the hands and feet revealed the classical osteitis cystica changes. A skiagram of the chest showed prominence of the hilar shadows, which is typical of sarcoidosis, but there was no evidence of the more classical multiple nodular opacities in the lungs, there was also calcification of glands in the left hilum, indicating a previous tuberculous infection. The Mantoux test was negative, as would be expected in sarcoidosis. A skin biopsy was not done since the diagnosis was not in doubt.

Between 1938 and 1947 the patient reported many times at the Royal Infirmary. Her general state of health remained excellent and she had no complaints apart from the disfigurement. Ultra-violet therapy and deep x-ray therapy did not improve the skin lesions. A photograph taken in 1943 is reproduced to indicate the appearance at that time (Fig 1). In June, 1947, she was admitted with a view to instituting calciferol therapy. Fig 2 demonstrates the state of the skin lesions before the administration of calciferol. The lupus pernio had become slightly worse since 1943, and a new patch had appeared on the upper lip. The fingers were also more

FIG 1—Showing the erythematous induration of the lupus pernio in 1943. The appearance was similar but less marked in 1938.

FIG 2—June 1947 before calciferol therapy. The lupus pernio is more extensive and an additional patch has appeared on the upper lip.

involved with ulceration of the skin in several areas. It is clear that the condition had been slowly progressing since the time of her first visit in 1938.

Calcium metabolism was investigated for the first time, with the following results: serum calcium, 10.6 mg per 100 ml; serum phosphorus, 3.9 mg per 100 ml; alkaline phosphatase 5 units (King), acid phosphatase 3 units (King); calcium balance normal. Hence despite the radiological changes in the bones there was no disturbance of calcium metabolism.

The BSR was 3 mm in 1 hour (Westergren) indicating the absence of rapid tissue destruction. Haemoglobin, red blood cell count, white blood cell count and differential count were essentially normal. The blood urea was 47 mg per 100 ml.

An interesting phenomenon was observed on performing a 1 in 1000 Mantoux test. No reaction was visible after the

customary 48 hours, but a definite strong positive was present after 72 hours. The same delay was found with 1 in 100 tuberculin. The previous Mantoux test in 1938, was given as negative, but it might not have been observed for more than 48 hours. There is no mention in the literature of a delayed positive in sarcoidosis. It may be that this phenomenon has resulted in some cases being given as Mantoux negative when in actual fact they are delayed positive.

Calciferol therapy was started with 100,000 units daily by mouth in the form of high-potency "ostelin" tablets. This was continued for 15 days (total, 1,500,000 units), when the appearance of violent toxic effects compelled stoppage of the drug. The toxic effects were similar to those reported by Dowling, Gauvain, and Macrae (1948)—namely, thirst and polyuria, constipation, headache, tiredness, loss of appetite, and sickness. There was no rise in the serum calcium, indicating once more that toxicity is not directly related to biochemical changes. The blood urea, however, rose to 60 mg per 100 ml.

During the period of the toxic effects—three weeks—dramatic improvement occurred in the skin lesions. The erythematous induration of the lupus pernio largely disappeared and the patient no longer felt difficult about appearing in public. The gross lesions in the fingers did not improve to such an extent, but the swelling was reduced and the ulceration which had appeared in the last year cleared up. The slighter lesions of the toes also showed some improvement. It is interesting to note that the main clinical improvement occurred during the period of alarming toxic effects. When these had settled down calciferol was administered again in reduced dosage (50,000 units every second day), but the patient was still intolerant, and treatment was suspended after two weeks. Nevertheless the clinical improvement has been maintained (see Fig 3).

FIG 3—September 1947 two months after cessation of calciferol therapy. Apart from residual deformity of the nose the face is almost normal in appearance.

### Comment

It has been pointed out that, in the treatment of lupus vulgaris, calciferol may "flare up" a tuberculous lesion elsewhere (Dowling and Prosser Thomas, 1946; Dowling, Macrae, and Jones, 1946; Powell, Pearsall, and Wigley, 1948). This may also apply in sarcoidosis, since a radiological follow-up in the present case shows slight progression of the osteitis cystica changes during the period of improvement of the skin lesions. The radiological appearances in the chest have not altered, but the patient's bronchitic symptoms have become worse. In view of this unfortunate tendency calciferol should not be used in the treatment of sarcoidosis unless the skin lesions are of sufficient degree to justify the risk.

Peterkin (1947—personal communication) has found that, apart from "flaring up" a distant lesion, calciferol may cause extension and ulceration of the lupus pernio. It is interesting that in the present case during the first week of therapy the patient complained of tingling in the facial lesion and the erythema became more pronounced, thus giving rise to considerable anxiety. This is another risk which should be kept in mind when calciferol therapy is contemplated.

### Summary

A case of Boeck's sarcoidosis is presented in which the skin lesions had been slowly progressing for nine years and in which therefore, sudden spontaneous improvement was not expected.

The administration of calciferol in the form of high potency ostelin tablets resulted in dramatic improvement of the skin lesions. The main improvement occurred during a three-weeks period of severe toxic effects unrelated to the level of serum calcium.

The relationship of sarcoidosis to tuberculosis is discussed. It may be that they are the same disease. The response of the skin lesions of sarcoidosis to treatment with calciferol resembles that of lupus vulgaris, this being another point in favour of a close relationship.

In view of the risks of "flaring up" a sarcoid lesion elsewhere and of causing sudden extension and ulceration of the skin lesions, calciferol should not be used in the treatment of sarcoidosis unless the skin lesions are extensive and disfiguring.

A delayed positive tuberculin reaction is described in sarcoidosis.

I am greatly indebted to Professor Charles Cameron for his advice and criticism and for the photographs taken in 1947. I am also indebted to the Department of Radiotherapy, Edinburgh Royal Infirmary, for the photograph taken in 1943. I wish to thank Dr W. D. D. Small for permission to publish the case.

## ARSENICAL ENCEPHALOPATHY DURING TREATMENT OF TROPICAL EOSINOPHILIA

BY

BALBIR SINGH, M.B., B.S. Punjab

(From the Main Hospital Jamsheerpur Bihar India)

Prebble (1946) made an extensive survey of the literature on arsenical encephalopathy during treatment of syphilis and reported 187 cases of encephalopathy among Indian troops treated for syphilis as in-patients. He concluded that Indians are particularly susceptible to the condition.

He referred to a report by Glaser and Immermans on two non-fatal cases of encephalopathy which had received arsenic for conditions other than syphilis. Lees (1937) also observed this condition among cases of disseminated sclerosis and Hodgkin's disease after the administration of an arsphenamine product. Viswanathan (1947) reported the post-mortem appearances in a patient with tropical eosinophilia who developed encephalopathy after two 0.3-g injections of neoarsphenamine. He, however, did not state whether syphilis was definitely excluded before treating the case as tropical eosinophilia. A further case of tropical eosinophilia in which encephalopathy developed after two 0.3-g injections of neoarsphenamine and death occurred is described below.

## Case Report

A Tamil mess cook aged 26 was admitted to 48 Indian General Hospital on Oct. 8, 1946, with a complaint of cough and breathlessness on exertion. The chest showed rhonchi all over it. A skiagram revealed changes associated with chronic bronchitis but no evidence of tuberculous infection. The total leucocytic count was 12,400 per cmm, with 61% eosinophils—i.e., absolute eosinophilia of 7,564 per cmm. The Wassermann reaction and Kahn test were negative. Tropical eosinophilia was diagnosed and 0.3 g. of neoarsphenamine was given on Oct. 24 and on Oct. 27. He complained of fever and shivering

after the second injection, and became dull and apathetic on Oct. 30. The temperature rose to 103.8° F (39.9° C), a blood film showed no malaria parasites. He suddenly became restless and began to have convulsions on Oct. 31, later he became delirious and finally coma supervened. His respirations were stertorous, eyes fixed, pupils dilated, and the reaction to light was sluggish. There was no neck rigidity. Abdominal reflexes were absent, deep reflexes were exaggerated, and plantar response was flexor. Blood pressure was 150/85, blood urea 60 mg per 100 ml. Blood films showed no malaria parasites and urine contained no sugar or acetone. Coma deepened, and he died within eight hours of the onset of acute symptoms. Necropsy was performed ten hours after death. All organs, except the central nervous system, lungs, and liver, were within normal limits.

**Macroscopic Appearances.**—The pia arachnoid all over the brain was congested and meningeal vessels were full. Cerebral grey matter was hyperaemic, and small blood vessels in the white matter of both hemispheres were congested. The choroid plexus was very engorged. No haemorrhages were detected on the surface of the brain or on section. The pleural cavity contained no free fluid or adhesions. The lining membrane of the right and left bronchi was congested. Bronchioles were slightly dilated, their mucous membrane was congested, and they contained mucopurulent secretion. The lungs showed no evidence of bronchopneumonia on palpation or on section. The liver was normal in size, and the cut surface revealed no change.

**Microscopical Appearances.**—Brain.—Examination revealed lymphocytic infiltration of the perivascular spaces and of the substance of the brain tissue in the vicinity of the capillaries. The capillary endothelium was swollen. Liver cells showed fatty change and foci of necrosis infiltrated by lymphocytes. I have no record of the histopathology of the lung. Cerebrospinal fluid taken during necropsy showed the following findings: total cell count, 280 cells per cmm, type of cells, 95% mononuclears, consisting of lymphocytes, plasma cells, and endothelial cells stained deposit, no organisms, protein, 180 mg per 100 ml, Nonne-Apelt reaction, positive 1, Wassermann reaction, one volume of 1 in 5 dilution showed partial inhibition of lysis, with one volume of 1 in 2.5 dilution, one volume of undiluted fluid, and two volumes of undiluted fluid lysis of cells was inhibited. The Wassermann test was carried out by Wylers's modification.

## Comment

This case was diagnosed clinically as arsenical encephalopathy. Post-mortem findings did not show haemorrhages or demyelination—important characteristic features of arsenical encephalopathy according to earlier writers. Prebble (1946), however, reported that these features were observed in only one out of 40 patients whose brains were closely studied by Kramer at the Central Military Pathological Laboratory, Poona. Microscopical appearances of the brain tissue in my case were similar to those described by him in some of his cases. The disease process in the liver was not so advanced that it could have caused death, but it was very probable that the damaged liver cells delayed the metabolism of arsenic as suggested by Friedman and Shinefeld (1941).

During life the patient gave no history of syphilis or of lapsed treatment. He had been attached to the hospital as a mess cook for three years and had not sought admission to a special treatment centre for venereal diseases during that time, nor did he show any signs or symptoms of meningeal, cardiovascular, or parenchymatous syphilis during life. Microscopy of the brain tissue also did not reveal any evidence of syphilis. Lymphocytic infiltration of the perivascular spaces has been regarded as a general form of central nervous system reaction and is not indicative of any one pathological condition. The blood Wassermann reaction and Kahn test were negative four days before he was put on neoarsphenamine. Cerebrospinal fluid collected during necropsy, however, gave a positive

Wassermann reaction Technical error was excluded by repeating the test on the same fluid, and cross-checking was afforded by three other tests on the fluid—namely, protein, total number of cells, and globulin All three were increased Absence of evidence of syphilis during life and on necropsy raised a question whether the positive Wassermann reaction was a biological false positive result This is very probable, but could not be definitely decided, as spinal fluid was not examined during life

Reynolds (personal communication) states that of the many conditions in which the biological false positive reactions have been reported in the spinal fluids encephalomalacia is possibly the only one which suggests that post-mortem changes can cause a false positive reaction in cerebrospinal fluid Stokes *et al* (1944) mentioned cadaver blood as one of the conditions giving false positive serological reactions Thomson (1947) quoted Bertolozzi, who found positive reactions in sera of a large percentage of 50 corpses whose blood he examined, but Kolmer (1928) stated that blood collected before bacterial contamination takes place would not give false positive reactions I could not find any reference in the literature to the false positive reaction in cerebrospinal fluid collected after death Four other cerebrospinal fluids that were collected after death and examined by me two to three days later showed a trace of blood and were found to be anticomplementary It is hoped, however, that those who have facilities will report on the incidence of false positive reactions in cerebrospinal fluid collected after death

### Summary

A case of arsenical encephalopathy in an individual in whom no evidence of syphilis could be established during life or on necropsy has been described

Absence of evidence of syphilis suggested that the positive Wassermann reaction of the cerebrospinal fluid collected ten hours after death was a biological false positive

Royal Manchester Children's Hospital

Coarctation of the aorta and patent ductus arteriosus are now recognized as defects which are amenable to surgical treatment, but the opportunity seldom arises of treating them simultaneously The following case is reported because of its rarity, the development of characteristic signs at an early age, and the electrocardiographic findings

### Case Report

The patient had been treated for pink disease at the age of 2 years 4 months The presence of a systolic murmur was noted and the diagnosis of congenital heart disease made, but the precise defect was not determined When seen on Nov 27, 1947, at the age of 7, she presented typical signs of aortic coarctation She had always been a quiet child and disinclined to take much exercise, but cyanosis had not been observed Her nutrition was poor and she was undersized for her age

A systolic murmur of a rumbling character was audible at the apex and a soft systolic murmur was heard along the left border of the heart and to a less degree over the praecordium A more pronounced systolic murmur could be heard over the whole of the posterior thorax but was maximal over the scapulae The blood pressure in both arms was 140/70 The femoral arteries were imperceptible and blood pressure readings could not be obtained In the stooping posture arterial pulsation was visible and palpable medial to the vertebral border of the left scapula The electrocardiogram showed right axis deviation (Fig 1) X ray films of the chest revealed

FIG 1—Electrocardiogram taken on Nov 27 1947

notching of the ribs and a double shadow in the region of the aortic knuckle The possibility of a patent ductus was anticipated because of the right axis deviation (Gilchrist 1947), although there was no systolic diastolic murmur

### Operation, Nov 28, 1947

Cyclopropane and oxygen were given through an endotracheal tube and closely fitting face piece connected with a rebreathing system incorporating the Waters absorber With the patient in the right dorso lateral position a curved incision was made below the left breast from the edge of the sternum opposite the third costal cartilage to the posterior axillary line A flap of skin and pectoral muscles was reflected up and the chest opened through the third interspace with section of the

third costal cartilage. The chest wall was more vascular than normal, but not nearly so vascular as in two adult cases of aortic coarctation.

On examination of the mediastinum the aortic arch was felt pulsating forcibly, but below a point 1 cm distal to the left subclavian artery there was no pulsation and a slight systolic thrill was felt. The mediastinal pleura was incised and reflected to expose the main arteries and the vagus nerve (Fig 2). An aortic coarctation, marked by a narrowing of the exterior and by a palpable thickening of the wall, was found 1 cm beyond the left subclavian artery, and a small patent ductus, suspected clinically, was attached to the aorta near the level of the coarctation. The ductus was about 5 mm in diameter and proved very friable, during its mobilization and division it tore in the angle of junction with the aorta, and the ligature cut through it at the pulmonary artery end. These difficulties not encountered in any of ten uncomplicated cases of patent ductus treated by ligation, took some time to overcome, but the blood loss was not severe. The aorta and left subclavian and intercostal arteries were mobilized without division of any of the latter.

A Blalock type of clamp was applied across the aorta and left subclavian artery and a second clamp to the aorta 3 cm below the coarctation. Two intercostal arteries were controlled

Fig 2—Showing findings at operation

by bulldog clips. The coarctation was resected and found to be almost complete, admitting only a fine probe. The opening of the ductus was immediately distal to the coarctation. The ends of the aorta were anastomosed by two stay sutures and a single running suture of black silk on an eyeless needle. The suture passed through all coats and an endeavour was made to get square apposition of the cut ends of the vessel.

On removal of the clamps there was slight leakage from the right side of the suture line, but this was easily controlled by a patch of fibrin foam. The chest was closed and the air aspirated from the pleural cavity by a needle inserted intercostally above the wound.

#### Progress

The patient was nursed in an oxygen tent for a few hours. Four days after operation 80 ml of blood-stained fluid was aspirated from the left pleural cavity. Convalescence was complicated by a swinging temperature which became normal two days after stopping penicillin and sulphamezathine. She was allowed up eighteen days after operation and subsequent progress was uneventful. Five days after operation the blood pressure in the arms was 118/80 and the femoral and popliteal pulses were palpable. Two months later the arm blood pressure had fallen to 90/58. The generalized systolic murmur disappeared immediately after operation, but a low-pitched rumbling systolic murmur has persisted over a limited area near the apex. The significance of this murmur is uncertain, but it may be due to some degree of mitral stenosis.

At the time of writing the patient is a very lively, healthy-looking child, and the parents have commented on the great

improvement in her general condition and activity. There has been a striking increase in the muscular development of the lower limbs. An electrocardiogram taken on Oct 24 1948 (Fig 3), showed that right axis deviation still persisted.

Fig 3—Electrocardiogram taken on Oct 24, 1948

#### Discussion

In published series (Abbott, 1928, Bramwell, 1947) the ductus was patent in only about 10% of cases of aortic coarctation of the adult type. The double lesion is therefore very rare. In our case the early appearance of a well-developed collateral circulation indicated a severe degree of coarctation, and the ultimate prognosis without operation was regarded as poor. In this connexion the literature shows a mortality rate of about 50% before the age of 30 and about 70% before 40. The presence of a patent ductus presumably increases the risk.

In cases of aortic coarctation the electrocardiogram usually shows a left axis deviation, the right axis deviation seen in our case is therefore noteworthy. Gilchrist (1947) has suggested that the explanation of this finding lies in the presence of a patent ductus arteriosus opening distal to the coarctation. In these circumstances the blood is believed to flow from the pulmonary artery to the aorta, thus throwing an additional load on the right ventricle. Our case supports Gilchrist's theory, though the small calibre of the duct and the persistence of the right axis deviation eleven months after operation suggest that this is not the full explanation. In bringing the ends of the aorta together no attempt is made to secure eversion of the edges as practised by Gross, since it is felt that anatomical apposition of the coats gives a stronger union. Crafoord passes the sutures down to but not through the intima, it was felt, however, that this practice increases the risk of a dissecting aneurysm. The rate of blood flow in the aorta seems to be an ample safeguard against clot formation over the sutures, a belief confirmed by observations in dogs (Gross and Hufnagel, 1945).

We are indebted to Mr D W Purser for his drawing.

In *Whereas They Were Blind* Dr R M Macphail describes the ophthalmic work of a medical missionary in India. In 1894 his father founded the Bamdiah Mission Hospital in spite of the scepticism of colleagues and the timidity of Indians unused to the ways of European medicine. However, in 1947 over 8,000 patients were treated there and nearly 7,000 operations were performed. The pamphlet is handsomely illustrated and is obtainable for 1s from the Foreign Mission Committee of the Church of Scotland, 121, George Street, Edinburgh.

## STEROID METABOLISM AND FRONTAL LOBES

BY

F REITMAN, MD, DPM

Director of Clinical Research Netherne Hospital Coulsdon  
Surrey

The 17-ketosteroids are end-products of steroid metabolism, their source being the adrenal cortex. The daily urinary 17-ketosteroid output is fairly constant—3.5–14.6 mg in 24 hours for adult normal women and 9.4–20 mg in 24 hours for adult normal men (Patterson, McPhee, and Greenwood, 1942). Hemphill, MacLeod, and Reiss (1942) investigated the 17-ketosteroid values before and after brain operations, in particular bilateral prefrontal leucotomy (lobotomy), in six cases, and found that after the third post-operative month the urinary 17-ketosteroid excretion rises, indicating an increased steroid metabolism. Commenting on their results, they advanced the theory that an interference with the nervous pathways between the frontal lobes and the hypothalamus may influence the anterior pituitary, which in its turn alters the pituitary adreno-gonadal functions.

The cerebral control of steroid metabolism is of clinical as well as physiological importance, and the above-quoted conclusions have been reinvestigated in 12 cases. All the patients were females at the period of sexual maturity, and all had undergone bilateral prefrontal leucotomy, performed with a rotating-blade leucotome of 25 mm cutting diameter. The urinary 17-ketosteroid output was followed up fortnightly for three to four months, except in the case of one patient who, after leaving the hospital, was inaccessible for the repeated investigations. The pre-operative and 3–4-monthly post-operative values are tabulated below.

Case No	17 Ketosteroids in mg /24 hours	
	Pre-operative	3–4 Months Post-operative
1	15.1	11.4
2	6.1	4.4
3	14.6	10.9
4	10.0	6.5
5	13.2	4.8
6	11.0	—
7	14.2	4.2
8	10.9	10.5
9	23.6	14.0
10	20.3	19.5
11	12.4	9.6
12	9.3	8.4

The absence of the post-operative value in Case 5 has been explained. Cases 9 and 10 show high pre-operative values, but as the sample was taken at random they are retained in the series. It can be seen that the 17-ketosteroid output taken three to four months post-operatively is lower than that taken pre-operatively, in contradistinction to Hemphill and MacLeod's findings.

Further examination of our figures shows that the standard error of the mean difference is 1.05 mg/24 hours and Student's *t* ratio 3.71. For 10 degrees of freedom this is significant at the 1% level, thus the odds are 99 to 1 against its arising by chance. In other words, statistical evidence suggests very strongly that after bilateral injury to the prefrontal lobes the 17-ketosterone excretion is likely to diminish.

The hypothesis of other workers—namely, that the prefrontal lobes influence steroid metabolism—thus seems to be confirmed but the direction of quantitative alterations is found to be contradictory. While no concrete explanation can be offered for these differences, attention should be drawn to the fact that the technique of leucotomy

(lobotomy) varies from hospital to hospital, and the extent and localization of the operative incision at various levels may be responsible for the difference in findings. Further more, Hemphill and his collaborators' reported cases were males, whereas the case material just presented consisted entirely of females.

Reports on frontal-lobe injuries and on lobotomies emphasize a frequently increased sensuality. In the above reported case material three patients showed increased sensuality but no corresponding increase in the 17-ketosteroid excretion could be observed—a possible indication that the increased sensuality is not of neuro-hormonal genesis. In other words, the 17-ketosteroid values seem to be independent of the patients' psychosexual state.

To ascertain whether patients with frontal-lobe injury respond to stimulation in the same manner as "normals," 17-ketosteroid values have been studied on patients who had undergone leucotomy and on patients who suffer from a mild neurosis. These patients were stimulated by 8 gr (0.53 g) of pituitary whole gland in 24 hours, by 6 mg of intramuscular "prostigmin" in 24 hours, and finally by the administration of an erythema dose of ultra-violet light on the day the urinary 17-ketosteroids were collected. These experiments are still incomplete and numerically do not lend themselves to statistical examination, but the main tendencies of the results so far are as follows.

Administration of pituitary whole gland raises the 17-ketosteroid excretion, but administration of the prostigmin results in lowered 17-ketosteroid excretion. These findings might confirm a cortico-pituitary control of the 17-ketosteroid excretion rather than an influence through autonomic mechanisms. On administration of an erythema dose of ultra-violet light the 17-ketosteroid excretion increases, as was reported by Myerson and Neustadt (1939). No differences in responses were found between operated and non-operated cases.

I wish to thank Dr W T Griffith and Mr J P S Robertson for their collaboration and help.

## Medical Memoranda

### Haematoma of the Rectus Abdominis Muscle

Haematoma of the rectus abdominis muscle, especially the variety in which trauma is an inconspicuous factor and which is referred to as spontaneous to distinguish it from the traumatic variety, is very uncommon but of considerable clinical interest because it simulates very closely an acute intraperitoneal lesion.

### CASE REPORT

A widow aged 71 was admitted to hospital on Aug 3, 1947 complaining of severe abdominal pain of ten hours duration. There was sudden onset of "tearing" pain in the right lower abdomen. The pain was continuous aggravated by movement, and became steadily worse up to the time of admission. She vomited twice soon after the onset of pain. The bowels were opened before the attack and flatus had passed after the attack came on. Micturition was normal. There was a previous history of chronic bronchitis.

On examination the temperature was 99.2 F (37.3° C), pulse rate 120 and of poor quality, and respiration normal but somewhat laboured. The facies was pale and anxious, and the tongue moist and clean. The general appearance was one of moderate shock. Inspection revealed an ovoid swelling of the right lower abdomen. Abdominal respiratory movements were limited. The shoulder raising

test was too painful to carry out properly. Palpation confirmed that the swelling extended from the symphysis to the umbilicus, and from the midline to the right as far as the linea semilunaris. The shape was oval, with the large diameter in the vertical axis. The swelling was smooth, firm, and tense, without impulse, extremely tender, and did not move with respiration. Percussion of the swelling gave a dull note. Rectal and vaginal examinations and urinalysis were negative.

The case resembled an acute surgical abdomen, and torsion of an ovarian cyst or torsion of the omentum was a possible diagnosis. As mentioned before, the shoulder-raising test was too painful to carry out and no deduction was made whether the swelling was in the abdominal wall or was intraperitoneal, but it seemed more superficial than would have been expected of an intraperitoneal lesion. However, operation was decided upon mainly because a serious intraperitoneal lesion could not be discounted.

**Operation**—A right sub umbilical paramedian incision over the swelling revealed a bulging and dusky coloured rectus sheath. Dark, tarry blood clot exuded immediately the sheath was incised. A clot the size of a large grape fruit was removed from in front of and behind a longitudinal split in the rectus muscle which extended from umbilicus to symphysis. There was considerable bleeding swelling up from behind the rectus muscle in the region of the deep epigastric vessels, and this was only partially controlled by under-running sutures, so that packing was necessary. The wound was closed on either side of the pack.

The pack controlled the bleeding well and was removed after 36 hours. A full course of penicillin was administered. The wound healed satisfactorily and the patient was discharged 21 days later. The follow up revealed no obvious abnormality of the rectus muscle, which functioned very well.

#### DISCUSSION

That trauma in some degree or other is the exciting factor in all cases appears certain. But where this traumatic factor is slight—e.g., coughing (the factor in this case)—then there will be a predisposing factor, and the main ones seem to be (1) senility, with its degenerative changes in the walls of blood vessels, (2) debilitating illness, with its degenerative changes in muscle, and (3) pregnancy, with its effect of stretching the muscle fibres of the rectus abdominis and the deep epigastric blood vessels.

Correct diagnosis is seldom made, the most popular one being torsion of an ovarian cyst. Diagnostic points are a history of paroxysm of coughing followed by pain, with the early appearance of a mass which may steadily increase in size and which becomes more prominent and fixed on raising the shoulders. Operative treatment is usually undertaken because of the doubt in diagnosis, but where a definite diagnosis of haematoma of rectus muscle is made then there is the choice of conservative treatment. If the haemorrhage is already considerable or is progressing operation should be undertaken. Teske (1946) gives an overall mortality of 4%, and Thomas (1945) states that there is a 13% mortality rate in the obstetric group.

### A Case of Melaena Complicating Congenital Pyloric Stenosis

The following case of congenital hypertrophic pyloric stenosis is worthy of record on account of an unusual complication—melaena—occurring after operation.

#### CASE REPORT

A male infant aged 6 weeks, an only child, was admitted to the Royal Salop Infirmary on July 16, 1947. He had had projectile vomiting for over a week. He had been breast fed, but his mother had given him complementary feeds of half-cream milk food after each feed for a few days. The weight had risen from 7 lb 15 oz (3.6 kg) to 9 lb 6 oz (4.25 kg) before the onset of vomiting, but had fallen to 7 lb 4 oz (3.29 kg) on admission.

Congenital pyloric stenosis was diagnosed and operation was decided upon (July 21). The stomach was first washed out, and then under local analgesia a Rammstedt's operation was performed. There was a well marked pyloric tumour. In separating the circular muscle

fibre the duodenal mucosa was inadvertently opened and was sutured with fine catgut. In view of this perforation an intravenous saline drip was set up and feeding by mouth withheld until July 23, when half strength half cream milk food was given, the drip being discontinued on July 24. Apart from two small vomits he made good progress until Aug 1, when his weight was 8 lb 3½ oz (3.73 kg). He then started vomiting bile stained material, and this lasted two days, being relieved after gastric lavage and rectal saline. Feeding by mouth was resumed.

A temporary improvement occurred, but on Aug 5 vomiting recommenced and the stools were relaxed. There had been no pyrexia throughout, and no signs of peritonitis. On Aug 6 the stomach was washed out and rectal saline given. A course of phthalylsulphathiazole, one tablet four-hourly, was started. Next day he was given glucose feeds. A "dark brown" stool was reported. His weight was 7 lb 8 oz (3.4 kg).

On Aug 8 (the 18th day) the baby was collapsed, pale, and generally oedematous. A plasma transfusion was started. Soon afterwards a large melaena stool was passed. The haemoglobin was 30%. Blood was substituted for the plasma, and about 450 ml run in slowly. Next day a remarkable improvement had occurred and the oedema had disappeared. The haemoglobin was 92%. Phthalylsulphathiazole was discontinued. After several dark stools the motions had now become a normal colour. Feeding was resumed with half-cream milk food. No further vomiting occurred. Apart from one melaena stool on Aug 10 the motions remained normal. Unfortunately it was not possible to estimate the prothrombin index.

Further convalescence was uninterrupted, and the baby was discharged on Aug 26 weighing 8 lb 5 oz (3.77 kg). When seen again on Oct 7, as an out-patient, his weight was 13 lb 14 oz (6.29 kg) and his mother stated that he had remained well.

#### DISCUSSION

I have found only a few references to bleeding into the bowel in cases of pyloric stenosis. Meader (1936), quoting a case in which 'occult blood' had been found in the stools on the seventh day—gradually decreasing after a few days—commented: "Now it is not unusual for these patients to vomit fresh blood within 24 hours following operation or for some evidence of blood to appear in the first or second stool, but in our experience this phenomenon has not occurred as late as in this instance."

In my case the bleeding was severe, occurring on the 18th day, and was preceded by gastro enteritis. It was presumably due to ulcer. Infection was probably an aetiological factor. Possibly trauma, particularly as the duodenal mucosa was punctured at operation and subsequently sutured, determined the location of the ulcer.

If infection and trauma are regarded as aetiological factors in peptic ulcer (Illingworth and Dick, 1941) it is surprising that this complication is not more common in pyloric stenosis since infections of various kinds are not infrequent after operation and the mucous membrane is widely exposed after incising the seromuscular layers.

The importance of breast-feeding in pyloric stenosis in relation to prognosis is well established (Herzfeld and Wallace, 1935; Thompson and Gaisford, 1935; Tallerman, 1938; Levi, 1941; Williams, 1942). Levi (1941) reported a consecutive series of 100 breast-fed babies who underwent a Rammstedt's operation without a death and contrasted this with a series of 46 babies who were bottle-fed, of whom five died—all from gastro enteritis. Bottle-fed babies present greater risk of cross-infection owing to their longer stay in hospital, they are less well nourished and are more liable to suffer from dietetic disorders (Williams, 1942).

It is probably significant that my case was artificially fed immediately before and after operation.

I wish to thank Dr A. D. Rope and Mr A. D. Haydon, under whose care this case was admitted, for the opportunity of treating it.

## Reviews

### SURGICAL ENCYCLOPAEDIA

*British Surgical Practice* Volumes 1 and 2. Under the general Editorship of Sir Ernest Rock Carling, F.R.C.S., F.R.C.P., and J. Paterson Ross, M.S., F.R.C.S. In 8 volumes (with Index volume) (Pp 487 and 540 illustrated £3 per volume Index £1, carriage and packing extra.) London Butterworth and Co 1948

The production of a work making any pretence at being encyclopaedic when considering the whole range of surgical practice is indeed a formidable task but it is no less than this that Messrs Butterworth and Co are doing in publishing *British Surgical Practice* as a companion to their *British Encyclopaedia of Medical Practice*. The editors of such a work have not only to decide upon its general form and the proportional allocation of space for each subject, but, what perhaps is more important, upon the authors who are to participate in writing the sections. It is not always that the extreme specialist is the best author of an article on his subject, often his outlook will be rather too narrow to meet the needs of a book of this character. We therefore congratulate the editors in chief Sir Ernest Rock Carling and Professor Paterson Ross (assisted by more than 30 consultant and associate editors) upon their choice and decision in all these matters.

The aim of the work is described in the introduction. There are many surgeons who have no easy access to libraries, works of reference, or centres of teaching and research and it is for them especially that this work is intended. While they may have no intention of attempting the more recondite operations of the specialist, they should know what can be accomplished by the expert working with his team in optimal conditions. The work is not written for the expert though we believe it contains contributions which he cannot afford to ignore. From our perusal of the volume now issued we agree with the authors that "the work as it stands is a reliable guide to sound practice."

The first two volumes cover only the first two letters of the alphabet, but the whole is to be completed in eight volumes, with a separate index. It is rather surprising to find that so much of surgery falls under the headings A and B, but undoubtedly this is due to the use of the earliest alphabetical synonym for any condition—for example virilism under the heading 'Adrenal' sympathetic surgery under 'Autonomic System,' and so on. The books are particularly well produced, printed on a high-quality paper (very costly in these days) and contain an abundance of excellent useful illustrations including some in colour. The reproduction of the diagrams—always a good test of paper and printing—is very good. There is an attractive binding which fits the volumes for a proud place on the library shelf. The price of £3 a volume may at first seem rather high but examining the book will soon convince the prospective purchaser that he is getting good value for his money.

NORMAN C LAKE

### THYROTOXICOSIS

*The Clinical Picture of Thyrotoxicosis* By Peter McEwan, M.A., M.B. Ch.B. F.R.C.S. Ed. (Pp 127 illustrated 15s.) Edinburgh and London Oliver and Boyd 1948

Much has been written on thyrotoxicosis by both physicians and surgeons by the former because of the diagnostic problems involved and by the latter because surgical treatment has predominated. Mr McEwan's book comes at a time when treatment with thiouracil challenges surgery but as the author remarks opinion is in a state of unstable equilibrium. The book is largely an account of his own considerable experience without any attempt to review the literature, though the few references made are in generous terms.

He describes the main symptoms one by one in separate brief chapters and also certain rarer effects of toxic goitre which are of interest but should not generally influence the practitioner too much in his diagnosis of the condition. Mr McEwan thinks the condition is often missed and no doubt he is right. Sometimes it is because the goitre is very small though perhaps few

will agree with his assertion that toxic goitre is not infrequent without any actual increase in the size or weight of the gland. Sometimes the mistake is in the other direction, for although all goitres are potentially toxic, as he points out all goitres are not causing the symptoms which accompany them. In this connexion he briefly discusses neurosis in goitrous women. Most will agree with his views on basal metabolism estimation and many other aspects of the subject, but it seems unfortunate that the author did not have more collaboration from a medical colleague for the more strictly medical aspects of toxic goitre especially in the field of cardiology, despite his objection that patients are apt to be upset by a succession of doctors. However even this objection is likely to disappear with thiotherapy, and in a chapter on treatment Mr McEwan shows the breadth of his views by a very fair assessment of the value of this drug. This is a most readable book largely because it is a simple record of the author's own experience. Although it comes at a time when views on treatment are changing it will give the practitioner a clear clinical picture of thyrotoxicosis.

HAROLD COOKSON

### FIRST RECORD OF DISSEMINATED SCLEROSIS

*The Case of Augustus D Esté* By Douglas Firth, M.A., M.D. F.R.C.P. (Pp 58 6s.) Cambridge The University Press 1948

A patient's account of his own symptoms and sensations, and of his reactions to treatment, is always a document of some interest unless the writer happens to be a hypochondriac. The interest is enhanced when the author is an important personage and is still further increased when the disease which he describes is one previously unknown to medical science.

Augustus D Esté the illegitimate grandson of George III suffered from disseminated sclerosis for 28 years, and the manuscript diary in which he recorded his sensations came to light during a waste-paper drive in 1940. Augustus was born in 1794. His father was Prince Augustus, the sixth son of George III, his mother was Lady Augusta Murray (Lady D'Ameland). Some of the letters of this over-indulgent mother to her son at Harrow have been preserved, and those, together with his own record of subsequent life in the Army, reveal the psychological traumata of his childhood and adolescence which may have played a part in the aetiology of the disease which wrecked his adult life. His attempts to cope with the affliction from 1825, when he first complained of dimness of vision, until 1848, when he died after years of helpless invalidism, are clearly and faithfully recorded. They include visits to Ramsgate Bath, Pyrmont, and other health resorts, the prescriptions of many physicians, and the description of this vain quest for health is accompanied by an account of the symptoms which would be recognized to day as those of disseminated sclerosis. The disease was described by Sir Robert Carswell of University College, London, in 1836, and was separated from the medley of spinal paraplegias by Charcot in 1868. Nevertheless Sir Augustus D Esté was the first to describe the disease and it was certainly worth while to celebrate the centenary of his death by publishing an account of his life and writings. The task was ably undertaken by the late Dr Douglas Firth whose sudden death unfortunately preceded the appearance of this charming and useful little contribution to medical history.

DOUGLAS GUTHRIE

### 'FEVERS FOR STUDENTS

*Essentials of Fevers* By Gerald E Breen M.D., B.Ch. D.P.H. D.O.M.S. Second edition (Pp 351, illustrated 15s.) Edinburgh E and S Livingstone 1948

This new edition of Dr Breen's book is disappointing. It is true that it contains a description of the "essential" signs and symptoms of the common infectious diseases, but it can give the student or nurse who is new to the subject very little guidance in the handling of an individual case. This is very noticeable in the section on cerebrospinal fever for example where the account of the symptomatology is satisfactory, but the author does not emphasize the concept of meningococcal infection, and although he discusses the close resemblance

between the clinical picture of all forms of meningitis he does not describe the variations in therapy which different aetiological agents require. As a result the inexperienced person brought face to face with a case of meningitis is given little help in its immediate management. Again in discussing the treatment of enteric fever, he states that "very good results, however, have been reported from penicillin coupled with the sulphonamides and that streptomycin promises very well". Apart altogether from any discussion of the efficacy of such methods of treatment which the author might argue was outside the scope of the book, surely it is essential to be precise especially with the former, about dosage and spacing of treatment. Dr Breen disarms us in his introduction when he comments on previous criticism that the book does not contain enough for the student by suggesting that there is enough theory to meet his needs, yet it is not simply a lack of theory but a dearth of practical advice which disappoints. We can sympathize with him in his feeling that colour photographs can be misleading, but his own colour representations are not free from the same faults.

THOMAS ANDERSON

## A PIONEER

*Truby King the Man* By Mary King (Pp 355, illus 18s) London George Allen and Unwin 1948

A biography of Sir Frederic Truby King by his adopted daughter Mary King is welcome. In this book she describes his early life in New Zealand, his medical studies in Edinburgh, and his return to his native country. There he first of all completely reorganized the work of a mental hospital and in doing so became interested in farming and the rearing of domestic animals. His health was never too good in those early days and he and his devoted wife went on special leave to Japan. He became especially interested there in the widespread practice of breast feeding—a contrast with what was happening in other parts of the world where rearing on the bottle was becoming more and more popular. Returning to New Zealand he began his campaign to promote natural feeding. The chapter describing this attempts to build a bridge between Truby King's two main interests but the statement that he had observed that "a very large proportion of the mental patients under his care had been bottle fed" is really too naive.

The development of the educational system of "mothercraft" continued mainly through specially trained nurses, and the results in New Zealand are now well known. Missionary work in London was less successful and Miss King presents the controversial aspects of Truby King's views on bottle feeding formulas as if he must have been right and almost every other paediatrician in the English speaking world thoroughly wrong. However this attitude does not loom large enough to spoil the book. What Truby King taught on managing the infant on pre-natal care and on the supreme importance of breast feeding was of fundamental and lasting value. How he did this with the constant help of his wife, though harassed by ill-health and continual financial anxiety is a good story and it has been well told.

ALAN MONCRIEFF

Bell's *Textbook of Pathology* (sixth edition, Herr, Kimpton 50s) has an established reputation. One of its merits is its manageable size in spite of a remarkable amount of factual information being packed between its covers by the liberal use of the short simple sentence and full stop. There is little discussion or speculation on debatable subjects and, what is rather more important, no serious or sustained attempt to correlate abnormal function with abnormal structure, or clinical signs and symptoms with pathological changes. These criticisms apply to the scope of the book as a reliable guide to the hard facts of morbid anatomy and histology we can heartily recommend it. The illustrations, apart from some of the drawings are of excellent quality and well chosen and a special feature is the list of selected references accompanying each chapter. Most British pathologists would not agree that "most of the severe endemics of streptococcal sore throat have been shown to be due to milk borne infection the milk being contaminated from streptococcal mastitis in the dairy cows" (p 171) and acute yellow atrophy of the liver can hardly be described as a form of fatty liver (p 109).

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*La Dénutrition* By M Lamy and others (Pp 407 150 francs) Paris G Doin 1948

An account of the pathology, symptomatology, and treatment of malnutrition

*Molecular Architecture and the Processes of Life* By L Pauling BS MA PhD DSc (Pp 13 1s 6d) Nottingham University 1948

The Sir Jesse Boot Foundation lecture for 1948

*Die Hypertrophie und das Carcinom der Prostata* By T Hryntschak Vol 4 (Pp 125 Sch 35) Vienna Wilhelm Maudrich 1948

A practical manual giving clinical and operative details

*Lehrbuch der Spirometrischen Analytik und Diagnostik* By R Exner (Pp 308 Sch 80) Vienna Wilhelm Maudrich 1948

Investigations into the air capacity of the lungs in various diseases

*La Streptomycine Étude expérimentale et thérapeutique* By A Abruzzo (Pp 94 220 francs) Paris G Doin 1948

A study of the pharmacology and the therapeutic uses of streptomycin

*A Textbook of Gynaecology* By W Shaw MD, FRCS FRCOG 5th ed (Pp 660 25s) London J and A Churchill 1948

This well known textbook for students and practitioners has been drastically revised

*Streptomycin und Tuberkulose* By G Fanconi, W Löffler and others (Pp 357 30 Swiss francs) Basle Benno Schwabe 1948

Papers on the treatment of meningeal, pulmonary and tuberculosis with streptomycin

## INFECTIVE EAR DISEASE

The attention and interest devoted to any cause of ill-health depend upon the extent to which it interferes with everyday life. The patient suffering from a disorder that is not incapacitating may neglect it because of the time that would be taken up in having it attended to. On the other hand, the medical man may not always find it easy to give the time and attention to such disorders that he would wish. Some of these conditions of ill-health, though not in themselves mortal or even incapacitating, may, if ignored or inadequately cared for, have serious consequences. Among these is infective ear disease.

It has for a long time been realized by insurance companies and by employers who enter into permanent contracts with those whom they employ that infective ear disease is a potential cause of invalidism, and in consequence applicants with such disease are often rejected as unfit for insurance or employment. Before the recent war many of the larger educational authorities set up special clinics for the investigation and treatment of infective ear disease in school-children, and it was the general experience that regular, often daily, treatment under specialist supervision resulted in a temporary cure in almost three-quarters of the cases. The problem of regular visits to the clinic was solved by making it part of the school attendance, and the clinics were held during school hours. The children were seen daily by nurses with special otological training and could be seen weekly, or more often, by an otologist.

In wartime infective ear disease proved to be a serious cause of wastage of manpower in the armed Forces, despite the rejection owing to ear disease of 2% of all recruits examined by the National Service Boards. In one survey in England over 6% of the patients in four large military hospitals were there because of ear disease. Regular daily treatment by a specialist or a trained orderly was often possible in the Forces, and the value of this daily attention in clearing up the condition was proved again and again. In the Royal Air Force Banham personally treated cases of infective ear disease daily and found that 80% were soon cleared up.<sup>1</sup>

It seems certain that regular daily treatment is the best method of clearing up infected ears. In school-children and in the Services conditions are usually favourable for regular daily treatment even if it is extended over a long period. If nurses or orderlies can be trained to use a head-mirror or headlight, thus enabling them to treat the depths of the ear under direct vision, the value of the treatment is increased. In all these clinics otological supervision has been necessary though a weekly or bi-weekly

visit by the otologist may suffice. In civil life, however, daily visits to a clinic over a period of weeks would be impracticable for most adults, and very few hospitals have the trained staff to undertake such work on anything but a small scale. In order to explore the possibility of meeting the needs of the adult civilian population a pilot scheme was set up in a group of factories in the Birmingham area some three years ago by the Medical Research Council on the recommendation of their Committee to Advise on Medical and Surgical Problems of Diseases of the Ear. The help and co-operation were secured of the Industrial Health Research Board, a group of industrial medical officers, and the management, staff and workers of the factories concerned. Mr Colin Johnston was appointed to establish and develop this factory otological scheme, which, it was hoped, would indicate the size of the problem and whether it could be adequately treated within the existing framework of the medical departments of the factories. His report on the first eighteen months' work is presented in an abridged form in this issue of the *Journal* and it will be of great interest not only to otologists and to all workers in the fields of social and industrial medicine but also to the general practitioner, who better than anyone else should know the extent of the problem.

The incidence of past or present ear disease in the random sample of factory workers is surprisingly high. Johnston found active disease in 59% and evidence of former disease in 14.6% of 1,900 workers selected at random. The Sickness Survey found that in reply to questioning by trained interviewers 1.66% of those interviewed admitted to ear disease, though, as Johnston found in his survey, a large proportion of sufferers from infective ear disease are either unaware of, or unwilling to disclose, the fact. It seems likely from a study of all the available figures that the real incidence of infective ear disease is somewhere in the region of 5% of the population, in round figures based on the latest population estimate that is 2,500,000 people. This indicates how much an organized scheme for treatment is needed.

Johnston has shown that, given a certain minimum of skilled otological supervision, infective ear disease in factory employees can be at least temporarily cured in over 80% of the cases. The very nature of the disease makes relapse inevitable in some, and this is an added reason for regular treatment being readily available. Furthermore, these results, which are comparable with those already mentioned, have been obtained without any expansion of the medical and nursing services in the factories apart from a weekly visit from an otologist. Perhaps the most important finding of all is that daily treatment can be continued over many weeks without time off from work. So far as the workers are concerned participation has been entirely voluntary and both management and workers have realized the value of the results obtained and are keen to continue with the scheme. It is clear that the management of infective ear disease along these lines can be extended both in hospital, school clinic, and factory medical department without adding unduly to the burden of work. In this way much can be done towards solving the problem of infective ear disease.

## COTTON-DUST DISEASE

As long ago as 1818 Jackson<sup>1</sup> noticed that those who worked in the cotton industry, particularly cardroom workers, suffered from a characteristic respiratory disease. The U.S. Public Health Service has recently brought the whole subject up to date with the publication<sup>2</sup> of a full review of the literature. The authors of this work consider that there are four diseases for which cotton dust is responsible—mill fever, byssinosis, weaver's cough, and an illness caused by the endotoxin of *Aerobacter cloacae*. It seems more likely, however, that there are only two diseases, perhaps only one. Mill fever is almost certainly the early stage of byssinosis, and the remaining two conditions are very similar to other diseases caused by mouldy organic matter such as grain, flax, hemp, jute, and bagasse.

There are 36 recorded surveys of the health of cotton workers in many different countries, but the work that has been done in this country is certainly much more complete than that in any other. In 1862 Greenhow<sup>3</sup> described the diseases of cotton workers in a report to the Privy Council, and in 1932 the Home Office<sup>4</sup> issued the *Report of the Departmental Committee on Dust in Cardrooms in the Cotton Industry*. This report summarized all existing information about conditions in the mills, types of machinery in use, and the nature of the cotton dust. It included an account of the clinical and radiological examination of a group of workers at Ashton-under-Lyne who suffered from respiratory disease and the necropsy findings in a few fatal cases. In 1936 Prausnitz<sup>5</sup> reported to the Medical Research Council on respiratory dust disease in workers in the cotton industry, and last year Gill<sup>6</sup> described the process of carding and the symptomatology of the disease. Cotton is obtained chiefly from Egypt, America, and India, and arrives at the mill in tightly compressed bales which also contain much foreign material such as particles of leaf and seed coat, cotton hairs, fragments of mould, and fine sand. During the first process of cleaning the tightly compressed cotton is pulled off in layers and hand-fed into a machine called the "hopper bale opener". It then passes into the blowing-room, where a series of machines free it from most of the impurities. All these machines are enclosed in dust-proof covers, but the workers who clean them must protect themselves against dust by wearing suitable clothing and respirators. The clean cotton coming out of the blowing-room passes to the carding engines, and it is principally the strippers and grinders in charge of these machines who suffer from the disease. Usually each stripper and grinder is in charge of sixteen carding engines, each engine is cleaned four times daily by a vacuum process, and twice weekly it is brush stripped. The evidence is very strong that the carding process liberates the injurious dust which causes byssinosis and that the atmosphere is most dangerous in the immediate vicinity of the carding engine.

The usual history is that after working for several years in the dusty atmosphere the man has sneezing attacks and develops a dry and irritating cough with a tight feeling in the chest and restricted intake of breath. At first the trouble is temporary, and symptoms will disappear after a week-end's rest. But they return, and the disease in consequence has been called "Monday morning fever," "mill fever," and "factory fever." The worker is not incapacitated at this stage, and his breathing will become normal if he is taken out of the dusty atmosphere. After exposure to the dust for ten or more years, however, the worker begins to complain of more severe symptoms such as asthma and bronchitis, the breathing is shallow, and there is a small amount of sticky mucoid phlegm. He loses weight and develops a sallow complexion. Absences from work become more frequent, but improvement can still be brought about by transferring the worker to an atmosphere free from dust. In the last stage emphysema is severe, and there is great shortness of breath. Cough is troublesome, with mucoid or mucopurulent expectoration. When severely affected a man may stand with his hands pressed against his thighs to aid his breathing. The disease is incurable at this stage, and many of these workers die before the age of 50. The physical signs are those of chronic bronchitis and emphysema, the respiration is laboured, and the accessory muscles are brought more and more into use as the disease progresses. The thorax becomes barrel-shaped, and the patient tends to sit in a characteristic attitude with the body bent slightly forward, the legs widely spaced, and the hands placed on the knees. The vital capacity is greatly reduced, and the chest expansion may be less than 1 in. The radiographic appearances are similar to those of chronic bronchitis and emphysema, though the shadows radiating from the hilum are of greater density and indicate considerable fibrosis. Chronic bronchitis and emphysema are found at post-mortem examination, but there is no way of distinguishing the bronchitis of cardroom operatives from that which occurs in the general population. Dunn and Sheehan<sup>7</sup> have reported that dilatation of the right heart was frequent.

Weaver's cough was first described by Collis<sup>8</sup> in 1914, and Middleton<sup>9</sup> in 1926 confirmed that cotton weavers in Lancashire suffered from an acute bronchitis brought on by handling cotton fibre. This was an acute illness with fever, cough, and sputum, the residual symptoms might last for as long as two months. The moisture left in the warp was thought to be responsible for this disease because it encouraged an abundant growth of fungi during storage on the beams, when weaving began the workers breathed in a dust laden with conidia, spores, and fragments of mycelium. Neal and his colleagues<sup>10</sup> in the U.S.A. described an acute febrile illness with cough, dyspnoea, tightness of the chest, and more general symptoms among workers making mattresses from low-grade cotton and among workers in cotton mills and cotton-seed processing plants where there were high concentrations of stained cotton.

dust. They thought the condition was caused by the endotoxin of a Gram-negative bacillus, *Aerobacter cloacae*. This condition and weavers' cough, however, have a close connexion with other diseases caused by contaminated organic vegetable materials such as "farmer's lung," described by Campbell<sup>10</sup> and Fawcett<sup>11</sup> in Cumberland, and "threshers' lung" by Tornell<sup>12</sup> in Sweden and Hoffman<sup>13</sup> in Switzerland. Bagrisse disease<sup>14</sup> is also similar, and so is "broken wind" of horses. These may all belong to a single group with the same underlying pathology. It also cannot be denied that byssinosis may be an end-result.

## REPRESENTATION OF CONSULTANTS AND SPECIALISTS

The difficulties inherent in the representation of the interests of consultants and specialists in the National Health Service are being resolved. There seemed at one time to be a risk of serious discord, with the different groups representing consultants pulling in different directions. On the one side was the B.M.A., erroneously held by some to represent the interests only of general practitioners but having a well-tried machinery of negotiation and an experienced Secretariat. On the other were the Colleges and Corporations, academic and examining institutions standing for most but not all consultants, with little or no experience of negotiation in what is called medical politics, and having no machinery for this purpose. The inauguration of the N.H.S. presented consultants and specialists, almost for the first time, with the problem of collective decision and action in matters concerning them generally, particularly in relation to terms and conditions of service and, more particularly now, to the recommendations of the Spens Report. Some held the view that the Consultants and Specialists Committee set up by the B.M.A. should handle these matters, others that they were the responsibility of the Colleges and the Corporations. In any tug-of-war between the two it was plain that something would come apart, and that most likely the real interests of consultants and specialists. An intraprofessional conflict would have been disastrous, and this was fortunately avoided by a decision of the various bodies to confer round a table.<sup>1</sup>

In July representatives of the Royal Colleges, the Royal Scottish Corporations, and the B.M.A. set up an Exploratory Committee under the chairmanship of Sir Lionel Whitby. This committee met again last week at the Royal College of Surgeons and agreed upon a statement which is published in this week's *Supplement*. "It is essential," the first item runs, "in the interests of the consultants that a joint committee of the bodies concerned should be established to speak for consultants with one voice"—the word consultants including specialists. The joint committee will have two secretaries, one appointed by the Colleges and the Corporations and the other by the B.M.A. There will be 17 members on the committee, 6 appointed by the Consultants and Specialists Committee of the B.M.A. and 11 by the six Colleges and Corporations. On this committee both teaching and non-teaching consultants are to be represented. Provision is made for disagreement among the constituent bodies.

The task of the committee is to represent consultants and specialists in impending negotiations with the Government

and later to consider what form of collaboration should be established for the future. The joint committee will have met by the time this issue is published. The choice of its chairman is awaited with interest, for upon his skill and force as a negotiator much will depend.

## VITAMIN D IN SARCOIDOSIS

In 1840, at the St. Louis Hospital in Paris, Emery<sup>1</sup> was treating lupus vulgaris with cod-liver oil in doses of one litre daily. It can readily be understood why such heroic dosage enjoyed only a brief popularity, but it is strange that a century elapsed before his method was translated into the terms of modern therapeutics. Almost simultaneously Charpy<sup>2</sup> in France and Dowling and Prosser Thomas<sup>3</sup> in this country proved that large doses of vitamin D would cure lupus vulgaris in a high proportion of cases. Their results have been confirmed throughout the world, and, though the frequency of toxic reactions has been responsible for a note of caution,<sup>4</sup> it is likely that the method has already become the standard treatment for this disfiguring and troublesome complaint.

It was obvious that the use of vitamin D would rapidly be extended to other forms of tuberculosis and to that curious condition Boeck's sarcoid (lupus pernio). With the passage of time more and more clinicians are willing to subscribe to Schaumann's theory, published in many papers during the past 20 years, that sarcoidosis is a form of tuberculosis. The evidence in favour of this hypothesis has recently been reviewed once again by Frudenthal<sup>5</sup> pulmonary tuberculosis is the commonest cause of death in sarcoidosis, the metamorphosis of cutaneous sarcoid into lupus vulgaris has been repeatedly observed, although *Mycobacterium tuberculosis* is seldom obtainable from sarcoid lesions, isolation has been successful in 26 authenticated cases, and, finally, it has been found that serum from patients with sarcoidosis neutralizes tuberculin. The recently devised Kveim test—an intradermal reaction with sarcoid tissue—affects the argument but little, though Leider<sup>6</sup> considers it another point in favour of tuberculosis. Proof is still lacking, but there is little doubt that opinion now favours the tuberculosis hypothesis.

This view, together with the resistance of sarcoid to treatment, was adequate reason for the use of vitamin D in the disorder. Reports have hitherto been scanty but encouraging. Dowling, Gauvain, and Macrae<sup>7</sup> mention seven cases, of which six were improved. Curtis, Taylor, and Grekin<sup>8</sup> have treated five patients with doses of 200,000 to 900,000 i.u. of vitamin D<sub>2</sub> daily and have noted improvement in cutaneous, pulmonary and digital lesions. It is of interest that in a discussion on their paper Pinkus reported the activation of indolent lesions with doses of 1,000 i.u. daily, though healing with fibrosis took place when the dose was increased. In this number of the *Journal* Dr R. F. Robertson records an impressive result of vitamin D therapy in a woman with extensive lupus pernio, although only 100,000 i.u. daily for three weeks was given before toxic symptoms interrupted treatment. In his patient pulmonary symptoms were aggravated and the digital lesions changed little. It is worth recalling that pulmonary fibrosis, the sequel of healed sarcoid infiltrations in the lung, is responsible for the death of many of these unfortunate patients.

<sup>1</sup> Charpy J. *Brit J Derm Syph* 1948 60 121

<sup>2</sup> Ann Derm Syph Paris 1943 3 331 340

<sup>3</sup> Proc R Soc Med 1945 39 96

It is difficult to believe that vitamin D could do anything but accelerate this change, nevertheless it is a notable therapeutic advance to be able to relieve the hideous disfigurement of lupus pernio

### PENICILLIN BY INHALATION

In the last few years penicillin aerosols have been extensively used in the treatment of chest disease, but it is still difficult to assess their value, and it is not yet certain that the best methods of administration have been found. Garthwaite and Barach<sup>1</sup> have recently described their results with this form of treatment. They use a nebulizer fitted with a rebreathing bag, the latter being immersed in hot water, and also containing half a glass of very hot water, so as to provide a warm, humidified aerosol. The nebulizer is fitted with a baffle to eliminate the larger droplets and is connected to an oxygen cylinder running at the rate of 8 to 12 litres a minute. A device enables the patient to prevent the penicillin solution from being nebulized except during inhalation. In the patient's home a car-tyre foot-pump has been used instead of the bulky oxygen cylinder. The apparatus is usually attached to a glass mouthpiece, but in ill patients or in children an oronasal mask is used. The authors have experimented with continuous inhalation, the nebulizer being kept filled by a drip feed and the aerosol delivered either into a mask or into an oxygen tent. Calcium penicillin was found less irritating than the sodium salt, but crystalline penicillin, either the potassium or the sodium salt, has proved to be better still.

Usually a dose of 50,000 units of penicillin is given dissolved in 1 ml of physiological saline, and this is repeated three to five times a day. After each dose at least one, and preferably two, rinses of 0.5 ml of physiological saline are added to the nebulizer and inhaled to avoid waste. If this is not done it has been found that 5 to 10% of the dose of crystalline penicillin and about 20% of the dose of calcium penicillin remain in the nebulizer. Preliminary results suggest that higher blood and sputum levels may be obtained by using hypertonic 3% saline as a diluent. Bryson and Grace<sup>2</sup> suggest that the penicillin should be dissolved in a detergent such as alkyl dimethylbenzyl ammonium chloride, and put forward some evidence for their synergistic action *in vitro*. Similar claims have been made for another detergent, propylene glycol,<sup>3</sup> but so far the clinical value of detergents has not been conclusively proved. Garthwaite and Barach found them less effective than saline as diluents. In general two to three times as much penicillin had to be given by inhalation as by intramuscular injection to obtain comparable blood levels in healthy individuals, and it was more difficult to reach such levels in those with lung disease. The amount of penicillin in the sputum, however, averaged 461 units per ml one to four hours after inhalation of 50,000 units, and there is no doubt that inhalation gives far higher sputum levels than does intramuscular injection.

Clinical results are difficult to assess. Garthwaite and Barach observed some improvement following 37 out of 55 courses given for bronchiectasis and 20 out of 24 given for chronic bronchitis. The results were seldom dramatic, and it was not easy to separate the effects of penicillin inhalation from those of postural drainage and other measures. Cure was claimed in four out of five cases of acute lung abscess but only one of these had had no intramuscular penicillin. Although direct intrabronchial or intratracheal penicillin may prove of great value in lung

abscess,<sup>4</sup> it seems unlikely that penicillin inhalation can be more than a minor aid to treatment in this condition.

Most workers have found that penicillin-sensitive organisms disappear from the sputum during a course of penicillin inhalations, but the patient is not always any better for the change and often the organisms reappear after treatment has stopped. No doubt penicillin by inhalation will continue to be used for chronic bronchitis and bronchiectasis mainly for lack of anything better. Careful attention to technique is important, but in most cases results are unlikely to be either impressive or permanent.

### ACUTE POLIOMYELITIS IN PREGNANCY

During the Colorado epidemic of poliomyelitis in the autumn of 1946 Taylor and Simmons<sup>1</sup> observed 25 cases occurring during pregnancy. They found that the incidence of the disease was twice as great in pregnant as in non-pregnant women of the same age group and thus confirmed the similar observation made at an earlier date by Setälä<sup>2</sup> in Finland. Blackwell<sup>3</sup> recorded the case of a woman who without ill effect to herself nursed patients with poliomyelitis during an epidemic in 1946, but who one year later, when no longer working because she was pregnant, contracted the disease. It is difficult to reconcile this increased susceptibility during pregnancy, when the levels of oestrogen and progesterone in the blood are high, with the claim of Anderson<sup>4</sup> based on experimental work on mice, that both of these hormones protect against the virus of poliomyelitis. Similarly the suggestion that chorionic gonadotrophin is protective<sup>5</sup> is at variance with the fact that the incidence of infantile paralysis is greater in the first three months of pregnancy than in the non-pregnant woman. Taylor and Simmons suggest it may be that in pregnancy the increased congestion and permeability of the upper respiratory and digestive tracts make it easier for the virus to gain entry.

Nineteen of the 25 cases reported by Taylor and Simmons occurred in the first six months of pregnancy. Among these there were no deaths, and only two patients had residual paralyses. Of the six patients who developed the disease in the last three months of pregnancy three died, and the surviving three had severe residual paralyses. These findings agree with previous experience. A study of 195 cases collected from the literature showed that the mortality among 110 women who developed the disease during the first six months of pregnancy was 7%—the same as that for non-pregnant women in the same age group—but in the 85 women who developed the disease in the last three months of pregnancy it was 27%. In the absence of any obvious reason for the greatly increased severity of the disease in the last months of pregnancy Taylor and Simmons suggest that it is related to the "chronic fatigue of advanced pregnancy." Russell<sup>6</sup> pointed out, and Hargreaves<sup>7</sup> has recently confirmed, that physical activity of any kind during the pre-paralytic stage increases the danger of severe paralysis. But there is no reason to believe that the induction of premature labour would lead to better results for the mother, nor indeed is there any advantage in inducing abortion when the disease arises in early pregnancy.

There are two other facts about poliomyelitis occurring during pregnancy which are worth noting. First, the degree of maternal spinal paralysis has no serious effect on labour. The uterine contractions proceed in normal

fashion, and lack of voluntary muscular effort does not contraindicate vaginal delivery, caesarean section has probably been employed more often than necessary. Secondly, no case of congenital poliomyelitis has been recorded, but any passive immunity transferred to the baby from the mother does not last long, since poliomyelitis has occurred as early as the eleventh day of extrauterine life.

It is now generally agreed that poliomyelitis is becoming more a disease of the adult population. In the first 10 months of 1947, 174 of the 908 cases notified in London<sup>1</sup> alone were in females over 15 years of age, but surprisingly few case histories of poliomyelitis in pregnancy have been recorded in this country. In any future outbreaks such cases deserve careful study and record if only to confirm the findings reported elsewhere.

### POLIOMYELITIS VIRUS IN BLOOD

When Koprowski and his colleagues<sup>1</sup> reported the isolation of poliomyelitis virus from the blood of a human case they renewed the hopes of those who still considered that a systemic infection precedes the involvement of the central nervous system in this disease. The serum used was collected on the third day of illness from a patient with presumed poliomyelitis (non-paralytic). The conditions of the virus isolation were, however, unusual. Serum was injected intracerebrally into "dilute brown" agouti mice, after an interval of several days a healthy mouse was killed and a suspension of its brain inoculated into more mice. One mouse developed paralysis 22 days after inoculation with the second mouse-brain passage. The strain of virus appeared to be immunologically identical with the other true strains, Lansing, MEF1, and YSK, which after isolation from human patients in monkeys can grow in rodents by adaptation, and thereafter can still reproduce the disease in monkeys. Virus has been isolated from blood very rarely. Ward and his colleagues<sup>2</sup> were successful with only one of 111 specimens of blood. They endeavoured to concentrate the virus and used rhesus monkeys as experimental animals. The positive specimen was obtained about six hours from the onset of symptoms in a very mild non-paralytic case occurring during the height of an urban epidemic. Virus was found in a stool collected two days later. These workers also drew attention to the fact that the distribution of the lesions in the central nervous system does not correspond to that expected from indiscriminate spread of virus across blood vessels. The virus has been found occasionally in certain viscera—for instance, the spleen—and in the mesenteric lymph glands at necropsy. It is possible that there is active multiplication of virus in certain tissues and a spilling over into the blood stream.

The results of a recent investigation by Bodian<sup>3</sup> indicate that infection of the central nervous system takes place as early as the first rise of temperature in patients with the prodromal type of temperature curve. In the light of the evidence at present available the most probable route of entry of the virus is through the exposed ends of peripheral nerves and then along their axoplasm to the central nervous system. Bodian also concluded that the majority of the neurones were attacked at the same time and that at least in the early stages of the disease the spread of the virus in the grey matter does not occur by cell-body to cell-body extension but probably along axon connections. If these latter hypotheses are correct they account for much of the difficulty and disappointment experienced with the serum prophylaxis and treatment of poliomyelitis.

### MORE RESEARCH ON BAL

Interesting observations on BAL continue to be made. A surprising experiment was carried out by 'de Oreo' on four patients who were being treated for syphilis. He showed that the preliminary administration of BAL largely neutralized the curative action of 'mapharside' in removing spirochaetes from moist syphilitic lesions. After having completed the demonstration he then cured the disease with penicillin. Lusk, Braun, and Woodward have carried out a more important piece of research. They point out that among the many agents influencing the rate of induction of skin tumours in mice with 3,4-benzpyrene certain hydrolysing chlor-compounds, bromobenzene, and unsaturated acids have been shown to delay tumour formation. Crabtree<sup>3</sup> has suggested that these inhibitors react with -SH groups and make them unavailable for normal cellular metabolism. Since in his opinion the initial phase in the production of skin tumours is the fixation of the carcinogen to the -SH groups of the cell, it occurred to Lusk and his colleagues that BAL might combine with the carcinogen and so delay tumour formation. This they have demonstrated successfully in an experiment with comparable groups of 55 mice. Seventeen weeks after the application of benzpyrene 82% of control mice had developed skin tumours, as compared with 58% of mice anointed with BAL in addition to benzpyrene. This is a further step in demonstrating the importance of -SH groups in tumour formation.

### NUFFIELD COLLEGE OF SURGICAL SCIENCES

Lord Nuffield has once again combined wisdom with munificence in bestowing £250,000 on the Royal College of Surgeons for the purpose of building a residential college where young surgeons, particularly from overseas, may live while undertaking advanced study or research. It will be called the Nuffield College of Surgical Sciences and will be built on land adjoining the Royal College in Lincoln's Inn Fields. Lord Nuffield could hardly have chosen a more worthy object for his generosity than the promotion of collegiate life in a university city where it is conspicuously insufficient, and in particular for postgraduate medical students. Those living at the college will be within easy reach of teaching hospitals, museums, and other centres of learning, and will have unrivalled opportunities of meeting leading surgeons attending the Royal College and listening to their lectures and discussions as well as to those valuable suggestions informally mentioned over a cup of tea. The many visitors who have come from overseas testify to the leading position held by British surgery, and the College will complement the work of the recently endowed Sims Commonwealth Travelling Professorship in spreading the best British teaching throughout the world. Lord Webb-Johnson will have further opportunity for exercising his great administrative gifts in successfully speeding this project on its way.

The Council of the Royal College of Surgeons has conferred the honorary Fellowship of the College on Lord Nuffield, honorary medallist of the College, and on Professor J. R. Learmonth, surgeon to H.M. Household in Scotland and Regius Professor of Clinical Surgery and Professor of Surgery in the University of Edinburgh.

Sir Reginald Watson-Jones has been appointed Arthur Sims Commonwealth Travelling Professor for 1950.

# THE END OF COMPULSORY VACCINATION

BY

C KILLICK MILLARD, M.D., D.Sc.

M.O.H. for Leicester 1901-35

The year 1948 will ever be memorable in the history of vaccination in this country as seeing the end of compulsory vaccination of infants, a measure which has been the subject of such acute and bitter controversy for so many years. Having regard to the great importance attached to universal vaccination of infants as our "first line of defence," and to the firm belief that only by compulsion could this be secured, it is rather surprising that the proposal to abolish compulsion did not arouse more opposition. In the event the opposition was almost negligible.

## History of Compulsory Vaccination

Jenner's great discovery was made just at the end of the eighteenth century, and the practice of vaccination gradually came into favour in the early part of the nineteenth. In 1840 an Act was passed providing for free vaccination by public vaccinators, to be appointed for the purpose by Boards of Guardians, but this was only permissive.

It was in 1853 that vaccination of infants was first made compulsory. By an Act passed in that year every parent who refused or neglected to have his child vaccinated within three months of birth was made liable to a fine of 20s. and costs. Thus compulsion was in force (theoretically) for 95 years, but it was only really in operation for part of that time. The Act provided no machinery for enforcing the law, but this omission was remedied to some extent in 1861, when Boards of Guardians were empowered to appoint vaccination officers for the express purpose of instituting legal proceedings against defaulters. Six years later, in 1867, a further Act was passed consolidating previous Acts and making the penal clauses more stringent. In the debate on the third reading Sir Thomas Chambers in opposing it, made this prophetic utterance: "I am persuaded that when the Bill is passed an agitation will commence which will never cease until the Act is repealed." It has taken 81 years for the prophecy to be fulfilled.

## Opposition to Compulsion

*The Leicester Revolt*—With the passing of this Act active opposition began. An Anti-compulsory Vaccination League was formed in London, and branches soon followed in a number of provincial towns. The movement was greatly stimulated by the numerous prosecutions for default which took place. Fines were imposed, and as many refused to pay, distraints on goods or imprisonment followed. The first parent to go to prison was a William Johnson, of Leicester. At a public meeting after his release he was presented by his admirers with a silver watch. This meeting may be regarded as the beginning of the movement against vaccination in Leicester, which became so strong that it led to the town being regarded as the "Mecca" of the antivaccination movement throughout the country.

After the serious smallpox epidemic of 1870-1, part of the pandemic which swept over Europe, the appointment of vaccination officers was made compulsory, and the authorities in Leicester, as elsewhere, attempted to enforce vaccination more rigorously. Prosecutions in the town increased from two in 1869 to over 1,100 in 1881, the total for the twelve years being over 6,000. Of these 64 had involved imprisonment and 193 distraints upon goods, the latter often being effected with much difficulty owing to popular sympathy with the defendants. All classes of the community were represented among those who set the law at defiance, and those who were prosecuted were regarded as martyrs. Ultimately in 1886, the Guardians decided by an overwhelming majority to cease prosecuting for vaccination default, and thereafter the vaccination laws became a "dead letter" in Leicester. As a result the number of vaccinations rapidly fell off, and for the past 40 years have averaged only about 5% of the births.

*If Vaccination was Objected to*—It would be a mistake to regard this widespread hostility to vaccination as merely the

result of organized agitation. Primarily it was due to the serious after-effects and injury to health of which many people had had personal experience in their own families, or believed that they had had, and which undoubtedly were much more common in those days of arm-to-arm vaccination, when the importance of asepsis was unknown or little understood. Even after glycerinated calf lymph had replaced the use of lymph taken direct from another infant's arm public vaccinators were required to do the operation much more "thoroughly" (four "good" marks) than is the case to day, and "bad arms" were not uncommon. To be compelled to have a healthy and beloved child vaccinated when it was sincerely believed that injury to health might follow seemed to many parents to constitute an intolerable interference with individual liberty.

*The Conscience Clause*—In 1897, in consequence of persistent and growing agitation and following the strong recommendation of the Royal Commission, new legislation was passed which included the famous "conscience clause." This enabled parents who could satisfy two justices in court that they conscientiously believed that vaccination would be prejudicial to the health of their child "to obtain exemption from the law." Nine years later the obtaining of exemption was made much easier by substituting the making of a statutory declaration before a magistrate or commissioner of oaths for having to go into court. The effect of this loop-hole, which was very largely taken advantage of, together with the fact that by this time smallpox had greatly decreased, led to a steady and continued fall in the percentage of children vaccinated.

## Warnings of Disaster to Come

Naturally, grave warnings were uttered regarding the great risk which the country, in particular the town of Leicester, was running. The then M.O.H. for Leicester, Dr Tomkins, in his annual report for 1888, wrote as follows:

"The sad feature about the whole business is that it is the young children of the town who are growing up in thousands unprotected and are running a risk to their lives. They have but to come in contact with the least breath of infection of smallpox to at once catch this loathsome disease."

No doubt, had I been M.O.H. for Leicester at that period, without the experience since obtained, I should have been as much alarmed as Dr Tomkins was.

Similar warnings were re-echoed by medical experts throughout the country. Dr J. C. McVail (1886), a recognized authority wrote:

"The antivaccinators of Leicester, having to a great extent thrown off the armour of vaccination, are waging a desperate and gallant, though misguided, conflict against the enemy. But in Leicester, when its time arrives, we shall not fail to see a repetition of last century's experiences, and certainly there will afterwards be fewer children left to die from diarrhoea. It is to be hoped that, when the catastrophe does come, the Government will see that its teachings are duly studied and recorded. Leicester has had little chance of getting its immunity tested."

## The Leicester "Experiment"

*Was it Ever Really Put to the Test?*—It is now 62 years since those words by Dr McVail were written. During this period smallpox has on many occasions been introduced into the town and three times it has attained to epidemic prevalence. When the first epidemic occurred in 1893 the outbreak was duly reported upon for the Government by Dr S. Coupland, and he was constrained to admit that "the facts would seem to show that in this epidemic at least the natural liability to smallpox, unaffected by vaccination, was not so great as has been supposed." There have been two subsequent epidemics—which I reported upon—but nothing in the nature of disaster has occurred, although on one occasion a sudden outburst took place without warning when 53 cases occurred in one week, followed by 21, 34 and 48 in the next three weeks. Then the outburst subsided almost as quickly as it had arisen, and six weeks later only one case occurred. The remarkable feature of this outburst was that no clue whatever could be obtained to its cause. For the first fortnight, until secondary cases arose, none of the cases could be traced. No link between any of them was discovered. They were scattered over the greater part of the town, regardless of age, sex, or occupation,

indiscriminately as if the infection had literally dropped from the clouds—which indeed it may have done if there is anything in the theory of aerial convection for there were a few cases of smallpox in the hospital prior to the outbreak. But it at least afforded the chance of testing Leicester's immunity' called for by Dr McVail. At that time infant vaccination had been abandoned for 17 years and at least 90% of the child population were unvaccinated. A certain number of school children were attacked, as of persons in other age periods, but no school outbreak occurred nor were any schools closed.

*Its Lessons*—The abandonment of infant vaccination in a large town like Leicester over a long period of years has undoubtedly provided that 'control experiment' which is so necessary if any theory is to be really tested. It is worth while, therefore, to consider what lessons are to be learnt from it. The two most important lessons are

(1) That mentioned by Dr Coupland and referred to above—viz., that the natural liability to smallpox is not so great as has been supposed. This is not to say that smallpox is not a highly infectious disease, it is probably the most infectious of all zymotic diseases, and very few persons are naturally immune to it. But there is a limit to its infectiousness, and it has been shown in Leicester that it does not "pick out" the unvaccinated persons in a community to nearly so great an extent as has often been alleged. It was quite expected that when smallpox did visit Leicester it would fall with special severity upon the unvaccinated children. McVail expressly prophesied this. Yet during the 34 years that I was MOH for Leicester, over which period more than 700 cases of smallpox (major and minor) occurred in the town, only 12 infants under 1 year of age were attacked, of whom three died. Incidentally some of these cases, including all the deaths, were under the age limit for vaccination, so that they cannot all be fairly attributed to neglect of vaccination.

(2) The second important lesson to be learnt is the efficacy of modern methods of prevention in controlling the spread of smallpox irrespective of the vaccinal condition of the population. This again is quite contrary to formerly accepted teaching. It does not mean, of course, that smallpox will never spread in an unvaccinated community—it will do so even in a so-called well vaccinated one. The fact is that it is not possible in practice to maintain any general population in a really well vaccinated condition—at least not in a democratic country. To do so would entail the repeated vaccination of every individual several times during his lifetime, and this is clearly impracticable. In the British Army the rule now is for each man to be revaccinated every five years when on home service and every two years when abroad.

### Why the Prophets were Wrong

Looking back it is interesting to consider why medical experts were so mistaken in their prophecies of disaster to come if universal vaccination of infants were abandoned. It was probably due to the belief, then so strongly held that it was infant vaccination, and that alone, which had brought about the great diminution of smallpox mortality that followed upon the introduction of vaccination. That this was clearly a case of cause and effect was reiterated in every textbook and in every course of lectures on public health. It was hailed indeed, as the outstanding triumph of preventive medicine. No wonder that medical students accepted it as an incontrovertible scientific fact. Dr McVail in his book, which was recognized as the standard work proving the case for vaccination, made use of a very telling diagram with which by judiciously selecting the periods it was possible to show a progressive decrease in smallpox mortality *pari passu* with an increasing efficiency in the enforcement of vaccination. Other authorities made use of similar diagrams and the apparent correlation inversely proportional between smallpox mortality and the amount of infant vaccination was at that time one of the principal arguments in support of the belief. We now know that this apparent correlation must have been a coincidence because smallpox mortality continued to decrease even after vaccination was decreasing also and this has now gone on for over 60 years. Obviously there must have been other causes at work which brought about the dramatic fall in smallpox mortality since the beginning of the nineteenth century\* and to that extent vaccina-

tion has for so many years been receiving more credit—perhaps much more—than it was entitled to.

It is not contended that infant vaccination had no effect in hastening the fall. The extent to which it did so is arguable. It would practically abolish mortality among vaccinated children, but against this it may have increased it in those children remaining unvaccinated and in persons of older age periods, owing to the detrimental effect of incomplete protection in encouraging the spread of infection by carriers (missed cases) which is one of the principal means by which smallpox is disseminated. Considerations of space make it impossible to pursue this further here. The point it is wished to make is that the fall in smallpox mortality which followed the introduction of vaccination would have occurred sooner or later even if vaccination had never been discovered.

### The Future of Vaccination

The official view is that, having regard to the great success which has attended voluntary methods in the case of immunization against diphtheria, infant vaccination will increase with the substitution of persuasion for compulsion. That this will actually happen however seems doubtful for two reasons. (1) In the case of immunization we are able to point out that diphtheria is a serious menace to child life while smallpox has ceased to be a menace, at least for the present. (2) With immunization we can truthfully say that it is "very safe" its effects are negligible and 'bad arms' practically unknown. Dare we say as much for vaccination?

Not so many years ago a married couple living on the outskirts of Leicester acting on advice had their two children vaccinated. Both developed post-vaccinal encephalitis and both died leaving that married couple childless rather unpleasant for those who gave the advice! Admittedly this case was very exceptional and the danger of developing encephalitis is less after vaccination in infancy than when the operation is performed for the first time at a later age. But other injuries to health are less uncommon. Having regard to these facts it will be difficult to work up much enthusiasm for active propaganda in favour of vaccination and without propaganda infant vaccination will almost certainly go. Unless smallpox should return and again become a menace it seems likely that in the future vaccination will be reserved for doctors, nurses, and sanitary staffs (and all these should be revaccinated much more often than is the case at present) for Service personnel for persons going out to the East and for the vaccination of contacts.

### The Outlook Regarding Smallpox

And lastly, what about smallpox? What are the prospects of the disease returning if infant vaccination does fall into disuse? Shall we see a repetition of the ravages in pre-vaccination times? It is doubtful if any authority really expects this to-day in spite of the prophecies made so confidently in the past.

Briefly the position is this: in Leicester during the 62 years since infant vaccination was abandoned there have been only 53 deaths from smallpox and in the past 40 years only two deaths. Moreover the experience of Leicester is confirmed and strongly confirmed by that of the whole country. Vaccination has been steadily declining ever since the 'conscience clause' was introduced until now nearly two thirds of the children born are not vaccinated. Yet smallpox mortality has also declined until now it is quite negligible. In the fourteen years 1933-46 there were only 28 deaths in a population of some 40 millions and among these 28 there was not one single death of an infant under 1 year of age. In passing it is to be noted that during the same period there were 11 officially admitted no fewer than 51 deaths of infants from "vaccinia" other sequelae of vaccination and post-vaccinal encephalitis. Had all the children born been vaccinated these figures would obviously have been much higher.

It certainly appears that the conditions of life in this country—public health, sanitation, standard of living, call them what we will—have so changed quite apart from vaccination that they are no longer congenial to the spread of major zymotic diseases which once caused a very heavy mortality in this

\*I am not alone in taking this view. Major Greenwood (1930) wrote: "(3) the use of this instrument (vaccination) has been one of the factors but not the sole perhaps not the most important, factor in modifying the epidemiological history of smallpox during the last hundred years."

country—e.g., scarlet fever, enteric fever, and typhus—have shown a decline in mortality as dramatic as that of smallpox, yet no one is alarmed lest these diseases should revert to their old-time mortality and certainly there was no vaccination to bring about their decline.

For those who still have misgivings about what may be in store now that compulsory vaccination has gone there is always this comforting thought: should major smallpox again invade this country and ever really get out of hand, we have one trump card to play which we have not got in the case of other epidemic diseases—viz., emergency mass vaccination of the whole population in the affected areas. Such a measure admittedly would be a very drastic one, and should certainly not be adopted except as a last resource. It is not a step to be taken in a moment of panic merely because a handful of cases of smallpox have occurred in a great city, but it would save the situation if effectually carried out as it could be if the situation were serious enough. For there is one remaining position in the provaccinist line of defence which is quite impregnable in spite of all the onslaughts which have been made upon it by the other side—viz., that a *recently vaccinated person does not take smallpox no matter how much he may be exposed to infection* (this does not include a person vaccinated during the incubation period). The exceptions to this law are so rare that for practical purposes they may be ignored.

### Conclusion

We suggest, then, that the abolition of compulsory vaccination is likely to be followed by a still further decline in the number of children vaccinated until in the course of a few years the child population of this country will be almost unprotected against smallpox so far as vaccination is concerned. The adult population of course never has been really protected.

As for smallpox, no one can foretell the future. Importations of the disease from abroad may occur at any time, as has always been the case, and there is also the possibility that some day a serious epidemic may occur, as in the past. I suggest however, that in view of the experience of the unvaccinated town of Leicester, and indeed of the whole country, during the past 60 years there is no real cause for alarm.

## THE ROYAL DENTAL HOSPITAL OF LONDON

The Royal Dental Hospital of London and School of Dental Surgery held its thirty-second annual "Clinical At Home" on Nov. 27, when many past students and visitors attended. The hospital, which now has 180 students, was extensively damaged during the war but has now been repaired, and several new departments and additions have been made, including a junior conservation department fitted with a number of manikin heads and drills for students and a new photographic department, the first of its kind in a dental hospital in this country. One of the most interesting demonstrations was in the speech therapy department. This department was established twenty-seven years ago particularly for patients with cleft palate, but with the vast improvements brought about by plastic surgery the cases that come under this heading now are only late or second operation patients and the work on speech therapy has been linked up with the orthodontics department. Orthodontists have felt that so long as their small patients continue to go about open mouthed and sucking their lips their work is largely thrown away. The speech therapy department therefore gives the patients exercises with a view to getting better muscular co-ordination.

At the annual dinner which followed the "At Home" the Dean of the School Mr H L Hardwick said that it had been felt for a long time past that the interests of students would be best served if the hospital were associated with a leading hospital and medical school and through the National Health Service such a fusion had now been brought about, the

hospital and school being in the St George's Hospital group. Mr Hardwick described the setting up of the new Fellowship in Dental Surgery by the Royal College of Surgeons as the most stimulating thing which had happened to the dental profession since the institution of the LDS. During the past year 32 former students had received the Fellowship. In the course of the evening the presentation of a cheque for over £500 was made to Miss H M Duncan on her retirement from the school after thirty-three years' service. Lord Webb-Johnson and Dr E W Fish replied to the toast of "The Visitors".

## TRYPANOSOMIASIS IN TROPICAL AFRICA

At a press conference held recently at the Colonial Office certain reports on trypanosomiasis and on the combating of the tsetse fly in East and West Africa were presented. Three of them have already been published by H M Stationery Office—namely, one on trypanosomiasis in British West Africa, by Professor T H Davey, of the Liverpool School of Tropical Medicine, a second dealing with Eastern Africa by Professor T A Buxton, of the London School, and a third describing the rural development and settlement scheme at Anchau (Zaria province, Northern Nigeria), by Dr T A M Nash, Government entomologist, Nigeria. A fourth and more extensive report by Dr Nash, on tsetse in British West Africa, is to be published shortly. Dr Nash and Professor Buxton were present at the conference to answer questions. It was stated that the ravages of the tsetse in Nigeria are so severe that only one-fifth of the country is really safe for man and cattle. One-third of the country is an endemic sleeping sickness area. The same is true of the Gold Coast. The whole of Sierra Leone is subject to tsetse, and endemic sleeping sickness occurs in one-tenth of that country. In the Gambia the conditions are similar. As for East Africa and the Rhodesias, Professor Buxton stated that the types of fly which inhabit narrow strips beside water have been controllable for a number of years, though often at undue cost, and in certain environments, though not in all, those which inhabit belts of bush can now be expelled. He did not hold the view that tsetse is everywhere on the advance. Where it is advancing, of course, the fact is known but the many areas in which it is retreating may not be as fully appreciated and may only be discovered by research. Dr Nash spoke of the Anchau scheme in which a corridor 70 miles long and 10 miles wide has been cleared and under the direction of the Sleeping Sickness Service of the Nigerian Medical Department 5 000 people have been moved from 45 hamlets and housed in 16 new villages and one town, while a further 60 000 people have been assisted by freeing areas of tsetse and providing good wells, schools and marketing facilities. This has been paid for by a £95 000 grant under the Colonial Development and Welfare Scheme. The name of the new town is an African word meaning "Walk in Health". The prices of the reports on the Anchau scheme, on trypanosomiasis in British West Africa, and on trypanosomiasis in Eastern Africa are respectively 3s 6d, 2s and 3s, and that of the more voluminous report on tsetse in British West Africa is 30s.

## TRAFFIC IN DANGEROUS DRUGS

### HOME OFFICE REPORT

The British Government has made a report to United Nations on the traffic in opium and dangerous drugs in Great Britain and Northern Ireland in 1947. The report, which is issued under the auspices of the Home Office, states that in this country known addicts number 164 men and 219 women and include 82 doctors, one dentist, one veterinary surgeon and three pharmacists. 10 doctors were convicted during the year for violation of the narcotic laws. Morphine and diacetylmorphine are the principal drugs of addiction, a few addicts use cocaine but the number addicted to this drug tends to diminish and fresh cases of addiction to cocaine are rare. It has become evident that pethidine must be regarded as a more usual drug of addiction than cocaine. Particular mention is made of two drugs "Metopon" (methylidihydromorphinone) was shown to be of medical value, and the Relaxation Order was invoked last year to permit of its

manufacture 'Amidone' was the subject of research in Germany during the war and has been developed on a commercial scale the hydrochloride being marketed under the trade name 'physeptone'. This drug while a powerful analgesic, is considered to be open to the same risks of improper use as pethidine, and steps were taken to place it under the control of the Dangerous Drugs Acts.

As for illicit traffic, it is stated that the only unlawful activity in narcotics which can be regarded as a traffic is the import by alien seamen of opium and Indian hemp and the use of these drugs by the smugglers themselves and their fellow countrymen in seaport towns, including London. Opium remains almost exclusively the drug of the Chinese smuggler and smoker. The traffic in Indian hemp originates with Indian, Arab, and negro seamen and extends by way of the dock areas of London to the West End, where it is peddled on a small scale. Particulars are given in the report of the exports of drugs from this country during 1947 and their destinations.

## RENAL, VESICAL, AND PROSTATIC CANCER LONDON SURVEY

Every year the Clinical Cancer Research Committee of the British Empire Cancer Campaign furnishes a statistical survey of cancer cases in the London hospitals, taking a different organ or region of the body on each occasion. A reprint of this survey with its innumerable tables, has been made from the latest annual report of the Campaign, which has already been the subject of a general review in these pages (July 31, p. 266). This year a detailed analysis is presented of 126 cases of cancer of the kidney, 451 of the bladder, and 399 of the prostate.

In the cases of cancer of the kidney the males outnumbered the females by two or three to one, and the mean age was just over 57. Haematuria was the commonest first symptom, except in the few cases of teratomata of the kidney, when the discovery of the tumour often preceded the onset of any symptoms. In more than one patient out of ten with renal carcinoma the primary was 'silent' and the first symptoms noticed were those due to metastases. Nearly three-fourths of the patients consulted a doctor within the first three months, and more than three-fourths of those who consulted a doctor were referred to hospital at once—higher figures than those for most regions of the body. Nevertheless, the growth had advanced so rapidly that 29.5% of the patients with carcinoma were found to have clinically recognizable metastases on admission.

In the bladder cases the ratio of males to females was three to one, and the mean age of the males was 63½ and of the females 66. Painless haematuria was the first symptom in 69% of cases. The proportion of patients who consulted a doctor within the first three months was only 54.4% and in 15% the disease was of over six months' standing when they were first seen. Of the patients who consulted a doctor 77.8% were referred to hospital at once, but 11.9% were treated symptomatically for more than three months.

The maximum incidence of cancer of the prostate was in the age periods 65 to 70. The first symptom of the disease was difficult or painful micturition in 60% but in 21% it was referred pain or some other symptom pointing to the possible presence of metastases. The proportion of patients who consulted a doctor during the first three months was 53.6%, but in about one-fifth of the cases the disease was of more than six months' duration when they were first seen. Of those who consulted a doctor 58.3% were referred to hospital at once and 17.3% were kept under symptomatic treatment for more than three months.

The main tables give the findings on examination, the methods of treatment, the five-year survival rate according to the stage of the disease and according to the therapeutic procedure chosen, the cause of death and the findings at necropsy.

The Division of Mycology of the New York Academy of Sciences held the inaugural meeting on Oct. 22. Dr. Norman Conant of Duke University gave a lecture on sporotrichosis. The following officers were elected: President, Dr. Frederick Reiss; New York University School of Medicine; Secretary, Dr. Royal M. Montgomery, Polytechnic Hospital.

## THE KING'S HEALTH

The following bulletin was issued from Buckingham Palace on Dec. 6.

The King's general health continues to be good, and he devotes a considerable proportion of his time to the conduct of affairs of State.

The process of restoration of the arterial circulation to the feet is proceeding slowly, and since the bulletin on Nov. 29 a further small but encouraging improvement has occurred.

In order to secure the rest and the warm environment which are indispensable for the re-establishment of the circulation, his Majesty is remaining in his apartments and spends most of the time in bed.

MAURICE CASSIDY	MORTON SMART
THOMAS DUNHILL	JOHN WEIR
J. R. LEARMONTH	

A more detailed bulletin was issued on Dec. 13.

Since the bulletin of Dec. 6 the King has made substantial progress.

Repetition of tests to measure the degree of arterial obstruction has given the following information:

In the left leg and foot the process of restoration of circulation has reached a stage which would be sufficient to permit some activity.

In the right leg and foot re-establishment of circulation, while progressive, has been less rapid and it is still of a degree which allows only strictly limited activity indoors.

The nutrition of the right foot is satisfactory.

With the passage of time and continuing care, further improvement in the circulation of both legs and both feet may be anticipated.

We have advised his Majesty to remain in London for the time being, but hope that early in the New Year it will be possible for him to continue his convalescence in the country.

We have thought it imperative to recommend his Majesty not to undertake any public engagements before the summer.

The improvements in the King's health which we are happy to record are in no small measure the result of his Majesty's willing submission to certain irksome restrictions and of his complete co-operation in all measures of treatment.

MAURICE CASSIDY	J. PATERSON ROSS
THOMAS DUNHILL	MORTON SMART
J. R. LEARMONTH	JOHN WEIR

A lecture on "Vision, Light, and Seeing" was given recently at the London School of Hygiene and Tropical Medicine by Dr. Matthew Luckiesh, director of the lighting research laboratory of the General Electric Company, Cleveland, U.S.A. The five primary factors in vision, apart from physiological and psychological were, said Dr. Luckiesh, the size of the object seen, the contrast between the object and its background, the brightness level, the distance, and the speed. In common optical practice a test chart was used to ascertain the power of the sight. The results of tests on this basis revealed the threshold or minimum conditions for seeing, and the normality or subnormality of vision was determined according to the size of the letters which could be read with ease and speed at a given distance. The letters on these charts were usually printed in black on a white background, thus giving the highest degree of contrast. But the contrast of an object against its background had, of course, a definite relationship to brightness level. The less the contrast the greater the need for a higher level of brightness. At a specified distance it had been found that a black object needing 10 foot-candles of illumination when seen against a background of white paper might require 100 against a contrast of grey cloth or 1,000 against black velvet. Dr. Luckiesh contrasted the eye strain involved in office work with that in work at a garment factory. The office worker, dealing with black print on white paper, spent her time on work involving a high degree of contrast, whereas the other might perhaps spend most of her time sewing black cotton on dark cloth. The brightness level needed in the two cases was obviously very different. The development of illumination, in the course of which the crude art of lighting up a space developed into a science, was best appreciated by regarding lighting as a chain of three links—namely, production, control, and specification of light. The first two of these had been developed over many years and had had for a long time a scientific basis. The third link, however, the specification of light—had been a crude makeshift at best, but a scientific establishment was necessary to complete the chain.

## Reports of Societies

### GASTROSCOPY

#### EXPERIENCE WITH MODERN INSTRUMENTS

At a meeting of the Medical Society of London on Nov 22, with Dr JENNER HOSKIN in the chair, the subject of discussion was 'Gastroscopy'.

Dr AVERY JONES said that modern gastroscopy dated from the development of the Wolf-Schindler instrument in Germany, which was introduced into this country about 1934. The instrument, a remarkable achievement, had been improved by Mr Hermon Taylor, and the time had now arrived to assess its value. Examination was carried out mostly under local anaesthesia, though it could be done under general. With adequate premedication with morphine or hyoscine discomfort was minimal. He had written to a number of colleagues to obtain their experience of the risks of the method, and although the survey was not complete, as he saw it the risk with the Wolf-Schindler instrument was very small—in about 1 in 2000 cases there had been untoward reactions, but very few of these were fatal. With the Hermon Taylor instrument, which gave much better definition and enabled a better view to be obtained, the risk was a little greater, and something like 1 in 700 cases had been accompanied by an untoward reaction.

The advantage of gastroscopy was the increased accuracy of diagnosis. It was a valuable supplement to x-rays. It might more frequently demonstrate a gastric ulcer, sometimes it would show a healed ulcer or it might reveal the presence of a diverticulum and not an ulcer at all. The method was also useful in controlling symptoms. The prognosis of a healed ulcer on the basis of gastroscopy was more accurate than such a prognosis on the basis of the x-ray picture.

#### Definition of Gastritis

Mr HERMON TAYLOR went further into the history of the gastroscope and recalled that in 1908 Souttar and Thomson at the London Hospital developed the idea of a jointed tube which could be hinged together. He showed a picture of one of these instruments made by Mr H S Souttar forty years ago, when the findings in twelve cases were described in the *Quarterly Journal of Medicine*. The method was rather overshadowed by the development of the opaque-meal examination, and no further progress was made until 1932 when Wolf and Schindler applied the principle of a flexible optical axis to gastroscopy. Their instrument was still in regular use but it had its disadvantages one of which was that it afforded no means of negotiating an obstruction. In 1939 he (Mr Hermon Taylor) had demonstrated an adaptation of the Wolf-Schindler instrument which allowed the gastroscope to be bent forwards at will and enabled a near or distant view of the mucosa to be obtained. The instrument could be flexed round so as to afford a view of a tumour in the pylorus.

The gastroscope had brought a new accuracy to the study of gastric conditions. Previously the diagnosis in radiologically negative cases was largely a matter of opinion based on the test meal, the examination of the stools for blood, and the clinical history with the result that all the cases came to be lumped together as 'gastritis'. The gastroscope exploded this conception of universal gastritis as explaining otherwise undiagnosed dyspepsias. Unfortunately the reports on gastritis led to a reaction against gastroscopy. Gastritis should be re-defined—it was an inflammation of the gastric mucosa recognizable by oedema, loss of translucency, petechial haemorrhage, excessive sticky mucus or mucus pus and perhaps erosion. Radiologically an unusual pattern or irregularity at the pylorus might simulate carcinoma and the gastroscope helped to elucidate this problem. Some authorities maintained that all gastric ulcers should be removed surgically because 10% of them became malignant. But if the gastroscope were used and the healing of the ulcer were watched there was no question of missing any malignant change. Mr Taylor added

that the examination by the gastroscope was not one to be undertaken lightheartedly. Mistakes and accidents did occur. The commonest mistake was one which he had made many times himself—that was in diagnosing malignant change in an ulcer on one gastroscopic examination.

#### Gastric Acidity

Dr A H DOUTHWAITE said that he gathered that Mr Hermon Taylor argued that with a high degree of rugosity there was a high degree of acidity and a large acid output, and conversely, if the rugosity was not well marked, the acidity would be lower and the output less. He questioned whether that was quite justifiable. Among the indications for gastroscopy he included investigation of the possibility of ulcer of the stoma in patients who had indigestion following operation. Again, the method might be of some value for experimental purposes in determining the effect of various drugs on the stomach.

Sir JAMES WALTON said that he would have liked to hear more from the openers about the comparison of the gastroscopic appearances with the clinical history rather than with radiological changes. He found gastroscopy of the greatest help when it was a question of deciding whether a partial gastrectomy should be performed.

Dr M D SHEPPARD spoke as one who had undergone gastroscopy. Unfortunately he had had no morphine or atropine. The sensations had been most unpleasant—a feeling of suffocation with excess of mucus.

Dr THOMPSON HANCOCK said that the factor of discomfort was a most important one, but he did not think that excessive premedication should be used. If morphine were used excessively a confusional state resulted in which it was impossible to obtain the patient's full co-operation, but with atropine and something else—perhaps codeine—co-operation was forthcoming and there was also a diminution in salivation. He had been impressed by the view that the acid secretion could usually be foretold by the size of the fold, but there were exceptions. In considering the dangers of gastroscopy, he thought the type of tube used was important. In his experience the long rubber finger-tip was much safer to pass than the metal tip, which was the standard type on the Hermon Taylor gastroscope.

#### Gastroscopy and Radiology

Mr DICKSON WRIGHT said that it was in 1915 that he saw gastroscopy done for the first time, it was carried out by William Hill, a British pioneer in this field who should be remembered. He himself first passed a gastroscope in 1933. Gastroscopy was sometimes misleading, and this had prejudiced him against it. He felt that it increased the risk of error in dealing with carcinoma of the stomach. He had known two patients recommended for operation, one for simple ulcer and the other for carcinoma, each showing a typical gastroscopic appearance, and yet they turned out to be the other way round—what looked like the carcinoma was the ulcer and what looked like the ulcer was the carcinoma. He placed reliance on a good x-ray picture more than on anything else in differentiating ulcer from carcinoma. X-ray technique would go on improving and at present gastroscopy was most popular in places where x-ray technique was not of high standard. In some brief further discussion Dr JENNINGS urged that radiologists should work in close co-operation with gastroscopists, a co-operation which would lead to much saving of time in x-ray departments.

Dr AVERY JONES agreed about the importance of clinical history and of radiology and other investigations. Gastroscopy could not be considered the final arbiter. It was only another investigation which added to the evidence available for summing up the case, but it did help. Mr HERMON TAYLOR also agreed that gastroscopy was only one of a number of investigations, but if a clear view was obtained then 'seeing was believing'. In his view rugosity indicated the capacity of the stomach—the level at which it could produce its secretion under the stress of emotion. It was not sufficient to form an opinion on the test meal itself.

## VAGINAL DELIVERY AFTER CAESAREAN SECTION

A meeting of the North of England Obstetrical and Gynaecological Society was held at Manchester on Friday, Nov 5, with the president, Mr J E Stacey in the chair.

Mr S B HERD (Liverpool) read a short paper on vaginal delivery after lower-segment caesarean section. This was based on a personal series of 18 cases seen in a single hospital under standard conditions within two years. Discussing particularly cases in which the caesarean section had been carried out after failure of trial labour in primigravidae, Mr Herd pointed out that the course of their next labours had resembled those of multiparae, the average duration being less than twelve hours. One important factor making for success was the more efficient uterine action in the second labour while a psychological factor probably also played a part. There had been no maternal or foetal mortality in these cases when delivered vaginally and no case of rupture of the uterus. In view of these good results it might be profitable to resort to caesarean section more readily in seriously delayed first labours. In all, the incidence of repeat caesarean section had to be repeated in 44% of the 18 cases, a lower figure than was generally reported. Once a caesarean, always a caesarean was not true of the lower segment operation, especially in the absence of gross pelvic contraction, although there did not appear to be any clinical method of detecting dangerous thinning of the scar in labour.

In the discussion which followed the president stressed that all women who had previously had a caesarean section must be delivered in hospital at all subsequent labours. Mr C H WALSH (Liverpool) quoted the results of a series of 70 cases, and emphasized the importance from the point of view of subsequent vaginal delivery of carrying out the lower segment operation in cases of placenta praevia. Dr REDMAN (Manchester) gave parallel figures for St Mary's Hospital.

At the same meeting Mr R M CORBET (Preston) described a case of adenocarcinoma in one horn of a uterus bicornis unicollis. Sir WILLIAM FLETCHER SHAW (Manchester) also described a case of adenocarcinoma of the vagina. Dr RICKARDS and Dr AUCLAND (Manchester) discussed a case of chronic vegetative serpiginous pyoderma affecting the umbilical, pubic, and vulval areas in a woman of 28. The predominating organism on culture was a staphylococcus, and the condition finally responded to curettage of the abdominal area and simple vulvectomy.

## SOUTH-EAST METROPOLITAN REGIONAL TUBERCULOSIS SOCIETY

The inaugural meeting of this society was held at the County Hospital, Orpington, on Nov 13. A draft constitution was discussed and amended and officers of the society were elected as follows: president, Brigadier H L Glyn-Hughes; vice-president, Dr W E Roper Saunders; chairman, Dr F Temple Clive; vice-chairman, Dr R Livingstone; hon. treasurer, Dr T W Lloyd; hon. secretary, Dr D L Pugh. It was intimated that the aims of the society are purely clinical.

More donors gave blood to the National Blood Transfusion Service during the June quarter of this year than at any time since the war reports the Ministry of Health. They numbered 98,055, including 24,075 new donors. In the same period 30,497 people joined the service—the highest number since March, 1947, bringing the total strength to 377,304 for England and Wales. The steady increase in blood transfusion is reflected in statistics for the June quarter which show that 77,148 bottles of blood were issued, a rise of some 21,000 over the same quarter of last year and of 31,000 compared with the same quarter of 1946. The number of bottles of dried plasma issued was 15,849 compared with 14,959 in the corresponding quarter of 1947 and with 13,906 in the corresponding quarter of 1946. To provide for future needs caused by increasing demands on the service and to reduce calls on existing donors, it is estimated that another 142,000 donors are needed in England and Wales.

## Correspondence

### Taking Children's Temperatures

SIR—I have been impressed by the convincing article of Professor Alan Moncrieff and Dr B J Hussey (Dec 4 p 972) showing that in infants a rectal temperature reading is the most reliable guide. Yet I wish I could feel persuaded that this should be the routine method for registering temperatures in young children. This article rather lightly perhaps dismisses the psychological objections to the practice as 'more theoretical than practical' but I think this is because there is no available observer to correlate the adult sexual difficulties of a patient with his medical treatment during infancy.

In 1924 my late chief, Dr David Forsyth, then a friend of Freud, taught that all interference with the bodily orifices should whenever possible be avoided, for, being "erogenous zones," they will quickly become conditioned—either positively or negatively—to interference and may later become responsible for various functional disturbances. In common with others of my generation I considered this teaching fantastic but I revised my opinion shortly afterwards when a nursery school in which I was interested decided to abandon their routine of taking daily rectal temperatures for the children were so obviously becoming fascinated and excited by the process. Since then I have seen numerous instances which confirm such theories yet they are all cases which would have been overlooked had I not been already made aware of these fundamental associations.

It would appear that the anal interference of infants can be accepted by them as a humiliating painful attack, when it may lead to symptoms such as vaginismus, tenesmus, etc., in later life, or it can be accepted as a guilty, seductive pleasure leading to a 'fixed' erogenous sensation in that area. Recently a Frenchwoman married and with children discussed her frigidity and confessed with extreme embarrassment that she realized how much she was missing when orgasm eluded her, for she could experience it readily with any anal contact. On questioning it transpired that, having rheumatic fever when she was very young, rectal temperatures had been taken for many months. She had never associated these incidents with her frigidity although she remembered them to be "very exciting." A middle aged woman who suffers from vaginismus on questioning (only) revealed the fact that her nursery training had been by means of enemata and suppositories, and (on pressure) confided in me that her two brothers were homosexuals, presumably of the passive type.

Such case histories are doubtless legion, but the fact that they are so unacceptable to us all may be one of the reasons why the syndrome receives so little recognition. Nevertheless, this point must be made that it is inconceivable that people with such disorders in adult life are going to return to their paediatrician and enlighten him—even if they could—about their subsequent difficulties. Medical psychologists who deal with sexual deviations are well acquainted with these facts which somehow do not penetrate to the nursing and medical professions at large. Some mothers recognize intuitively that any anal interference offends the child's privacy and it is interesting to find the association between homosexuality and faulty nursery training accepted by that very shrewd observer, Claud Mullins in his recent book *Crime and Psychology*.

Perhaps some medical psychologists would state their views on this important matter? If these facts are agreed to be true they should lead to modification of this practice in the leading children's hospitals. In my own view it is not justifiable to interfere with our infants in such ways except on an occasion where the gravity of a physical illness makes accurate recording of the body temperature really imperative—I am etc.,

London NW1

JOAN MALLESON

SIR—I was interested in the article by Professor Alan Moncrieff and Dr B J Hussey (Dec 4 p 972) on temperature recording in sick children and I consider the subject to be one of considerable importance whether the patients be children

## ECONOMY IN PRESCRIBING PROPRIETARY MEDICINES UNDER THE NATIONAL HEALTH SERVICE

*In a recent article (Practitioner, April, 1948, p 300) it was stressed that, in order to avoid wastage, it is desirable to prescribe proprietary medicines in amounts provided in the original containers*

*Some of our newer packings are :*

AURO-CALCIUM  
(calcium aurothiomalate)  
COLLOSOL CALCIUM WITH VITAMIN D (HIGH POTENCY)  
(50,000 I U vitamin D per teaspoonful)  
CROOKES HALIBUT OIL EMULSION FOR INFANTS  
(12 drops — 3,000 I U vit A, 800 I U vit D)  
LACTALUMINA  
(Colloidal aluminium hydroxide 6%)  
NEOFERRUM  
(Colloidal ferric hydroxide 10%)

Single ampoules and boxes of 6  
10 mg, 25 mg, 50 mg, 100 mg

4 oz

15 c.c. vials

6 oz, 12 oz

liquid 4 oz, 8 oz

tablets 50 250

*A complete list of packings is available, on request, in our illustrated*

# BELLADENAL

Antispasmodic .. Anticonvulsive  
:: Sedative ::

BELLADENAL combines the central sedative action of  
phenobarbitone with the peripheral antispasmodic  
action of the total levorotatory alkaloids (Bellafoline)  
of Belladonna leaves. Bellafoline is only half as toxic as  
atropine in doses which are therapeutically equivalent in  
their effect on the parasympathetic.

Each tablet of Belladenal contains

Bellafoline 0.25 mg  
Phenobarbitone 0.05 Gm

The components of Belladenal act synergetically with each  
other so that a powerful antispasmodic and sedative effect  
is obtained with comparatively small doses.

Full particulars and samples on request

or adults. Having been a hospital patient myself on a number of occasions in the past few years I have had opportunity to make my own observations on this question and have now as a consequence developed the deepest distrust of all temperature recordings in hospital. Their very low degree of accuracy unquestionably explains many unexpected rises and falls in the febrile chart and is liable to cause great confusion unless the possibility of error is constantly borne in mind.

In my opinion this inaccuracy is due to several factors. The method and site are important: axillary readings are useless and should be abandoned. The most practicable method for general use in adults is the buccal, but even this does not guarantee a correct reading, as in the majority of cases the thermometer is never left in long enough. To shake the thread down as far as it will go and then leave the instrument in for 30 seconds dead, as is so frequently done, is not good enough. 60 seconds is much better and 2 minutes or more better still.

Another factor with some bearing on the subject is that temperature recording is a routine and doubtless monotonous task. It is as a consequence frequently left to the junior nurse, who is often only too anxious to get the job over and done with as soon as possible. As a result it is skimmed: no discrepancy is appreciated in a pulse rate of 120/min and a temperature reading of 97° F (36.1° C), and the temperature reading is faithfully recorded as such. Even pulse recordings counted over 15 seconds are not highly accurate, and I have known a nurse to be as far out as 40/min in her recording. Doubtless nurses will object to spending a minimum of two minutes on each patient in a 30 bed ward, but surely it would at least be worth while taking the little extra trouble over pyrexial patients in whom the temperature chart is of great importance.

During a long pyrexial period extending over several months I have had opportunity to check and recheck these observations on myself. 30 seconds often produced little significant temperature rise, 1 minute gave a higher reading and 2 minutes or more frequently a reading of 101° F (38.3° C) or over. The wide divergence in hospital readings I noticed as a house surgeon first drew my attention to this subject. I found that out-patient department axillary readings often showed no fever, whereas readings I took myself in the same patient by leaving the oral thermometer in place for an adequate length of time produced a most significant rise, sometimes of 2° or 3° F.

I am sorry if I have dwelt unduly on this subject, already partly covered in the article published, but after underestimating one or two complicated cases of appendicitis by relying on the slipshod methods in general use among nurses I consider the matter to be one of fundamental importance. Anyone who has seen the obviously phony appearance of a temperature chart showing a neat row of blobs dead on the 97° F line throughout will agree that something is wrong with the temperature readings so frequently recorded in hospitals—I am, etc.

Edinburgh

ADAIR GIBBY

SIR—While the findings of Professor Alan Moncrieff and Dr B J Hussey (Dec 4 p 972) on the variation of the temperature as recorded in the axilla, groin, mouth, and rectum are of interest and importance I cannot agree that their conclusion that the axilla and groin should be discarded as sites for temperature readings is sound.

What is of importance surely in a temperature reading is not the actual reading but the extent to which the reading differs from the normal. If we accept and the fact is incontrovertible that the normal reading in the axilla or groin is lower than that in the mouth or rectum then difficulties in interpretation do not arise provided that the temperature is accurately recorded. For many years I have regarded a temperature of 98° F (36.7° C) in the axilla or groin as evidence of pyrexia. It should be a simple investigation to determine the precise range of temperature readings in these sites on a large number of normal children such as can be found in schools.

Particularly in general practice the mouth or rectum are thoroughly inconvenient sites for temperature readings. The difficulty of sterilization, the added time factor, and the unpleasantness of rectum manipulations militate against these sites. I agree that the axilla is a difficult area in children and in adults in which to be certain of taking accurate readings, but the error in infants is a perfectly easy, safe and accurate one. Children may be then subjects as far as the axilla

is concerned but it is always easy to bury the thermometer in a fold in the groin. May I add that the difficulty that is due to the fact that a thermometer does not register accurately in less than five minutes in the groin applies almost as much when it is used in the mouth—I am, etc.,

Manchester

BASIL LEE

SIR,—The discrepancy between mouth and axillary temperatures pointed out by Professor Alan Moncrieff and Dr B J Hussey (Dec 4 p 972) is an interesting fact that is surely appreciated by every G.P. if not by hospital physicians. No doubt many have used it to reassure anxious parents who are so impressed by the actual height of their child's temperature. What may not be so commonly realized is that local inflammatory conditions of the mouth (gingivitis, etc.) tend to increase this discrepancy. I have recently seen two children where the difference was nearly two degrees. One of them was being kept in bed as a P.U.O., till the nurse in charge noticed that axillary temperatures were always normal and examination of the mouth revealed a stomatitis. It would be interesting to know if this factor was operative in any of Professor Moncrieff and Dr Hussey's most striking cases, such as the child with purpura whose chart was illustrated in Fig 1.

To take rectal temperatures is obviously the rational and scientific solution, but perhaps this is differentially raised in cases of enteritis. Psychological trauma may be a mere bogey but the child certainly resents its loss of dignity for a while and greets further visits from the doctor with tears instead of smiles—I am, etc.,

Margate

T S STONE

### Neonatal Asphyxia

SIR,—I hope that the correspondence which has followed my letter (Oct 30 p 797) on neonatal asphyxia will ensure that the practical applications of Sir Joseph Barcroft's discoveries will no longer be neglected in midwifery teaching, practice or textbooks. All your correspondents have raised points of interest on which I should like to comment briefly.

Dr W Radcliffe's letter (Nov 13, p 878) recalls the 'sparklet' resuscitator, which was most successful when first introduced but whose popularity seems to have waned. I pointed out to Sir Joseph many years ago that the efficacy of this apparatus was almost certainly not due to the carbon dioxide but to the fact that the gas had been rapidly expanded from the sparklet bulb and was therefore intensely cold. It was the bitterness of the blast on the sensitive nasal mucous membrane and not the composition of the gas that was the effective agent. As soon as people in a well-meant attempt at gentleness began to warm the carbon dioxide its efficiency disappeared, and the very handy and effective device became discredited—through misunderstanding.

Dr A. H. Galley (Nov 13, p 878) brings both common and uncommon observations to reinforce Sir Joseph's demonstration of the great importance of cutaneous and other stimuli in restoring or initiating respiration, but it does not solve the problem, which I think is most important, whether the response to these stimuli persists when the respiratory centre is poisoned or inactive for if this is so it might help enormously in the treatment of asphyxia from nearly any cause except poisoning by cerebral convulsants. Incidentally I think he misinterprets the "sadistic attacks" which I presume to be the old-fashioned and often very effective spanking though blowing on the abdomen is often more effective still.

Drs E Lewis Butler and Sarah Butler (Nov 20, p 918) put the case for "coramine" (nikethamide) very well, and Mr W G Mills (Nov 27, p 956) points out its virtues and also some of the snags of injection into the umbilical cord, which is the route usually favoured by the textbooks. I have neither the experience nor the pharmacological skill to argue the case between coramine and 'cardiazol' (leptazol), but undoubtedly Professor Barcroft's experiments do suggest that the agent used should have semi-convulsant properties, and it is not usually considered that coramine is a convulsant, though Drs E L and S Butler state that they have seen spasm result from intracardiac injection. Cardiazol is, of course well known as a convulsant and used in convulsant therapy as a reasonably safe one, whileephedrine, which I have always used with it, has many pharmacological properties in common with it. (I should of course, like to have used all these drugs singly, but-

being a general practitioner my business has been to save life and not carry out experiments which might endanger it in the conditions of general practice, and when I have found one good drug I stick to it till it fails and I feel justified in trying another.)

But these two letters put together add something to the jigsaw. The fact that the injection, when given into the umbilical vein often has to be milked along it shows that this is a relatively indirect way of introducing the drug that it is introduced relatively slowly and perhaps uncertainly. I therefore agree with the Drs Butler about giving whatever drug is administered into the heart cavity, for one then knows exactly how much is given, it is easier, quicker, and more certainly sterile, and the fact that I have once had to give a whole millilitre of cardiazol ephedrine in this way before I got a response suggests that in some of these cases it needs a pretty strong concentration in the blood if some of these quite viable babies are to be saved. I also agree with the Drs Butler about the advisability of giving some of the drug intramuscularly also. Personally I always try this first and in most cases it is successful within a few minutes. If it is not, I go into the ventricle with the other 0.5 ml, knowing that the first dose will be useful in supplying a little more when the circulation gets going. I think that this may be the reason that Mr Mills is pessimistic about such treatment preventing neonatal respiratory troubles. There is probably need for more than the initial stimulus—quite apart from the possibility that cardiazol ephedrine would have given better results—and I find that nearly all the babies whom I have treated in this way cry very much more in the first 24 hours than normally. This does not seem to exhaust them in any way but does ensure thorough expansion of the lungs.

I would only add that experience with caesarean babies is not quite applicable to normal births. For some reason caesarean babies are much more liable than others to die rather quickly and inexplicably. I had a long talk with the late Professor Dougal on this subject some while before he died but beyond confirming that this was a fact he had no explanation to offer for it. On reflection, it suggests to me that the seemingly rather dangerous and prolonged anaemia of the brain during the passage through the birth canal may have some recondite but beneficial biological action, just as the apparently wanton destruction of erythrocytes soon after birth has been explained by Professor Barcroft as nature's way of providing a depot of iron to guard against anaemia. All these are intensely interesting as well as practical problems and perhaps observations in general practice may yet help researchers in their elucidation, though I greatly fear that the dead hand of Ministry of Health regulations may soon diminish our chances of making them—I am, etc.,

### Marxist Genetics

SIR—In his review of Lysenko's address on Soviet biology (Nov 13, p 862) Professor Darlington has adopted not without effect the hard hitting and harsh polemical style of his Russian *bete noire*. Lysenko's brand of evolutionary genetics—called variously Michurin Darwinism or Lamarckian dialectical materialism and here, for short, Lamarxism—appears from Darlington's onslaught as the outpourings of a charlatan and political sycophant whose biological views are subject to censure or approval by the Central Committee of the Communist Party of the USSR. However, one of Darlington's most telling points in support of this condemnation does not appear to check up at all with the text of the address. Darlington says that there has been a deletion of 'the notion previously advanced by Lysenko 'that there is no competition within species' and he makes the damning inference that this tenet of Lamarxism has been suppressed at the dictate of some Party expert as being at variance with orthodox Marxism. But in fact Lysenko sticks to this view as irritatingly as he apparently does to his other quaint opinions. He says (p 38) 'after a deep and comprehensive investigation I have come to the conclusion that there exists no intra-specific struggle but mutual assistance among individuals within a species and there does exist inter-specific struggle and competition and also mutual assistance between different species. No doubt mounting disgust at the crudity of style and argument rather than political spleen is responsible for the misstatement by the reviewer. The point is nevertheless of some interest as Darlington relies on it to 'catch out' the Western professor and counterparts in their Lamarxist contortions."

The 'deletion' he says, catches these Western imitators in the middle of the act with their eyes shut and not knowing whether to go on coiling or to turn over backwards. Darlington, largely on this particular point, does not spare his scorn at the Western acrobats 'playing at apology under the Soviet circus master'.

Surely this ill-directed polemic, which takes up a considerable portion of the review, is not calculated to help the ordinary reader or even those interested in genetics towards a calm and non-political approach to this problem. Has not the time arrived when we may expect from our leading geneticists reasoned criticism well documented and soberly expressed which by all accounts would easily demolish the feebly supported generalities and the long-exploded and irrational doctrines of the Lamarxists?—I am etc.,

Oxford

J S WEINER

### Pensions for Diabetics

SIR,—I read with interest the letter on the above subject from Dr R D Lawrence (Nov 13, p 875). Whilst appreciating his views it cannot be too strongly emphasized that all cases of diabetes occurring in the Service cannot be bunched together and dismissed because medical opinion can find no evidence that various extrinsic conditions are causal factors in its aetiology. Each case must be dealt with individually on its merits, and this point has been argued and won before the tribunals and the High Courts.

The question of war pensions is not entirely a medical one but in fact is largely legal. The royal warrant puts the onus of proof on the Minister of Pensions, and it is only right that he should be made to discharge this onus on the evidence in each particular case. It would appear that Dr Lawrence has approached this question of onus in the wrong way. The question is not whether you can find evidence to associate a disability with service but whether the evidence shows that the disability can be dissociated from service.

Another pot-hole into which one is liable to stumble when looking at a case from a medical point of view is the question of the interpretation of the words 'attributable to service'. Correct interpretation was given by the Court of Session in *Brown and others v Ministry of Pensions (War Pensions Appeals)* Edited by Chapman, p 464. The relevant passages are quoted hereunder.

'When, as in all these fourteen cases, the issue is whether it has been proved beyond reasonable doubt that a disease is not attributable to war service, it is vital to keep clearly in view what is involved in that issue. The use of the word 'attributable,' and the nature of the tribunal selected for the purposes of affirming or denying attributability, indicate in our view that the search is for causation no doubt, but not in the metaphysical or in the scientific sense but in the wider and more liberal sense in which 'the matter would be understood by the man in the street applying common sense standards'. The issue in *Yorkshire Dale Steamship Co v Minister of War Transport and Muir v L.N.E.R.* was very different, but the principle is in our view the same."

The following extracts from the same judgment also emphasize the fact that cases must not be decided wholly on the medical aspect (loc cit p 463).

In three of the cases (*Halbert, Martir and Heftu*) the account given of the proceedings before the tribunal suggests that a serious misconception prevails as to the judicial functions of the tribunal and its members. The cases state in detail the medical advice given to the tribunal by the medical member and the legal advice given to the tribunal by the legal chairman. That legal advice took the form of a statement that, because in terms of Article 2 (2) (b) of the royal warrant the Minister must in certain cases decide in accordance with the opinion of his medical officers, 'the same criterion' must be applied by the tribunal, and, in the absence of conflicting medical evidence the decision must be rested on 'the informed medical opinion on the facts as distinct from the non medical view,' unless new facts have emerged in evidence which destroy or throw doubt upon the medical view. The startling result of such advice would be that, whenever the medical member agreed with the view of the Medical Services Division as to the effect of the facts, the decision of the case would rest with the medical member alone to the exclusion of the other two members.

'If it had been intended for instance that medical questions relating to pensions should be determined solely by considerations

appealing to the informed medical mind,' the appeal would have been to a board of medical experts and not to a mixed tribunal

Finally, it would appear that even the Ministry of Pensions' Medical Services Division—and I venture to think many other medical men—are not in agreement with Dr Lawrence on the question of the amount of disablement arising from diabetes, as in all cases accepted for pension the percentage awarded by the Ministry is usually fairly high. These percentage assessments are, of course, given in accordance with Article 9 of the royal warrant which means that the assessment is on a comparison between the disabled member and a normal healthy man of the same age, not taking into account his incapacity for employment or any other external factor—I am etc

### Interinnomino-abdominal Operation

SIR—I read with interest the paper by Mr David Mitchell and Dr J A Baird (Nov 27, p 940) reporting a case of interinnomino abdominal amputation, and I should like to congratulate them on the excellent result. They say, however, that 'no case has been recorded in which a prosthesis has been fitted'. In October 1947 at the second International Conference of the Emergencies of Medicine and Surgery in Lisbon I reported and showed a film of a patient who had had a hindquarter amputation in December, 1945, and who was fitted with an artificial limb seven months later. This patient is walking well with one stick. A reference will be found in the Portuguese literature in the published *Proceedings* (2nd series, No 1, Lisbon 1948).

Since then a further hindquarter amputation has been performed, eighteen months ago and the patient, a male, is now also walking on an artificial limb and making good progress. These patients will be reported in the English literature in the near future—I am, etc,

Norwich

### Treatment of Placenta Praevia

SIR—We read with interest Mr W G Mills's article (Nov 20 p 896) on the conservative treatment of placenta praevia, and we must congratulate him and his colleagues in Birmingham on their excellent maternal and foetal results, which would be difficult to better. We would, however, like to comment on several points in his paper.

With regard to our views (*Edinb med J* 1947, 54, 504, 510) being regarded as reactionary we would point out in the most amicable manner that Mr Mills has subscribed to some of them. We did not condemn the expectant treatment of placenta praevia but sounded a note of caution as to its universal application. We note that in Mr Mills's series after the patient has reached the 37th week treatment is undertaken forthwith to avoid further unnecessary blood loss to the mother and possible foetal asphyxia from sudden haemorrhage. Mr Mills's conservatism therefore cannot be considered extreme. In our review we found that the foetus had to attain the birth weight of 6 lb (2.7 kg) to have a 90% chance of survival. In the cases delivered between 36 and 38 weeks only approximately half were up to this weight so in our view delivery at 37 weeks still carries a definite foetal risk.

Further in regard to our foetal mortality we would point out that we reviewed 505 cases over a period of six years and encountered eight foetal abnormalities which would influence our foetal mortality which is uncorrected by 1.6%. This is of course negligible in our cases but we mention it to emphasize the various factors which operate with regard to the number of cases reviewed. We are not statisticians but Mr Mills has had no case of foetal abnormality in his 100 cases and presumably such abnormalities are fairly evenly distributed throughout the population he may encounter those in a further 400 cases.

We would point out that we mentioned in our conclusions that one of the cases in our series died of a fatal vaginal haemorrhage six days after hospital admission. She was promptly delivered and treated with massive blood transfusion but was nevertheless to be considered for operation. No vaginal

examination was made, and placenta praevia was diagnosed after death. In the discussion on our paper Professor Fairlie mentioned a 'near death' during expectant treatment. We consider this evidence that on occasion 'catastrophic' haemorrhage can occur when no vaginal examination has been made.

We note with interest that Mr Mills stresses an adequate standard of nutrition among the patients as a requirement for expectant treatment. We would like to make the point that the nutrition of the patients in Glasgow leaves much to be desired, especially among women of considerable parity. This weighed very heavily with us in reaching our conclusions. We would repeat our view that in the average multipara in the large industrial area from which our cases come anaemia and malnutrition are the rule, and we are very loath to introduce any factor which may even to a slight degree prejudice the outcome from the maternal point of view.

Finally, we would make a plea for simpler classification of placenta praevia. We note that in Mr Mills's series the general procedure was to perform caesarean section in the cases where the placenta was palpated across the cervix or coming up to its margin and to rupture the membranes in the others. This also was the procedure generally followed in the cases in our series. Surely, therefore from the clinical point of view there are but two types of placenta praevia—those that can be felt across the cervix or up to its margin, and the others. We suggested in Edinburgh that severe and mild would cover the condition, but major degree and minor degree would appear equally suitable. Any further subdivision appears unnecessary and confusing—We are, etc,

Glasgow

HUGH STIRLING  
R A TENNENT

SIR,—In recent years excellent results have been achieved by the conservative treatment of placenta praevia, and the report of a series of 100 cases by Mr W G Mills (Nov 20 p 896) is impressive. The remarkable reduction in the foetal mortality without added risk to the mother reported by Macafee, Johnson, Mills, and others is likely to excite the enthusiasm of many obstetricians less favourably placed for this method of treatment. I well remember that such a foolhardy enthusiasm on the part of some obstetricians on the appearance of Macafee's first report resulted in some disasters. Most people forget that such achievements are not the result of one man's efforts. They are the results of full and persistent co-operation of the patients, midwives, practitioners and the nursing and medical staff of well-equipped and highly organized hospitals with facilities for immediate blood transfusion in liberal amounts and timely, safe, and skilled operation.

Every obstetrician must be alive to the environments in which he is practising and the type of patient he is to treat. There are vast populations in this world (e.g., in Pakistan, India, China, Africa and several other places) for whom the facilities obtainable in London, Belfast, or Birmingham do not exist. Many patients in my country, Pakistan, when admitted to the hospital are at first very co-operative and readily accept all conditions for treatment. But later on all of a sudden, they leave the hospital at their own risk. They lend themselves easily to vaginal examinations by ignorant midwives. Indeed, they even make their own vaginal examination, as was done by one of the patients undergoing expectant treatment for placenta praevia at the Lady Willingdon Hospital, Lahore. The medical practitioners too find it difficult to restrain themselves from making vaginal examinations and manipulations before sending the patients for hospital treatment.

Of the 200 cases of placenta praevia studied by me (Thesis for MS 1946) and treated during a period of 12 years (1934–45) only 14 patients received expectant treatment. Two of the 4 patients who left the hospital at their own risk were readmitted after 3 and 20 days respectively in a serious condition and died soon after admission. The obstetrician should carefully note Mills's statement: 'On several occasions there was a sudden loss of 15–20 oz (425–570 ml) of blood, usually in the middle of the night'. These haemorrhages did not prove catastrophic. But the obstetrician must carefully study his patients who may be unfit to stand such a sudden loss. Such losses may appear innocuous and yet may pave the way to a catastrophe during the third stage. Or they may

result in anoxia of sufficient degree and duration to cause permanent damage to the nervous system of the mother as well as that of the foetus resulting in psychic and nervous troubles in later life. Rarely even Simmonds's disease may develop.

To my mind the expectant treatment of placenta praevia is highly desirable provided all the requisite conditions are satisfactorily fulfilled. Above all blood transfusion should be used liberally not only to save life but also to prevent damage to the delicate nerve cells from anoxia—I am, etc

Isleworth Middlesex

M S QURESHI

### Resuscitation by Rocking

SIR—I was very interested in the article (Sept 18, p 554) by Dr F C Eve and the late Dr N C Forsyth on resuscitation of infants by rocking. My father, Dr L Welply, told me some twenty years ago how he used to revive newborn infants by wrapping them in a towel and swinging them down between his legs and up over his head—the height of the ceiling and other obstructions permitting. This is clearly an exaggerated form of rocking and if as Dr Eve suggests the rocking helps to expel stagnant blood from the infant's head my father's method must have done it even more efficiently.

When I was accoucheur at the London Hospital I used a milder form of the swinging method successfully on many occasions, and when I came out to China two years ago as consultant orthopaedic surgeon and was asked to organize the maternity services here while building alterations were being made to the new orthopaedic department I introduced the rocking method to my Chinese interns. The custom here has been to belabour the newborn infant with the flat of the hand until it cries, a method not conducive to recovery from shock.

My method is to wrap the newborn infant in two towels between which a warm hot water bottle is placed and so arranged that it lies behind the child's back. The left hand is then placed behind the infant's neck so that the occipital region is held between the extended thumb and index fingers and the infant's left shoulder is fixed by the curve of the little finger. The infant's body lies along the left forearm and its thighs are held by the right hand placed behind them. The infant is then held up to the left shoulder in the position commonly used for making babies eructate, and by swinging the left forearm outwards and downwards the infant can be swung through almost 180° into the head-downwards position, the left hand moving slightly with the thighs and the left forearm remaining almost stationary across the resuscitator's lower chest.

Resuscitation by this method can be continued almost indefinitely without fatigue as the bundle of infant, towels, and hot water bottle rest against the shoulder at the end of each up-swing. Besides lack of fatigue to the operator, the following advantages are claimed for this method: (1) The shocked infant is kept warm throughout. (2) Full use of the comparatively heavy infant's liver as the motive force for the movements of the diaphragm and lower chest are obtained. (3) The head-downwards position encourages all mucus and other fluid obstructions in the upper respiratory system to drain easily, and if this position is maintained for a few seconds periodically an attendant can remove them with a mucus catheter. (4) Air intake can be heard as the infant reaches the head upwards position, its mouth being very close to the operator's ear. (5) Spontaneous respiration can be felt by the little finger where it holds the shoulder from slipping. (6) The infant's colour can be observed each time it is coming up in the up-swing if a small area of the face is left exposed. (7) Except for the pumping action of the liver due to the swinging motion the infant's state of shock is not aggravated by the rough handling that all other methods of resuscitation entail.

Finally, may I add that it is my custom to inflate the lungs first by mouth-to-mouth respiration through several layers of sterile gauze, and I have yet to see a respiratory infection started as a result. It is remarkable how such infants obtain and maintain a good colour long before spontaneous respirations start, and in heavily anaesthetized or morphinized infants, due to prolonged anaesthesia or too recent an injection of morphine in the mothers their colour can be maintained pink by swinging as slow as 4–6 times a minute in many cases their heart beats remaining strong throughout. Furthermore if one decides to give oxygen the tube can be led through the towels to warm it, across the palm of the operator's left hand to steady it, and so to the infant's nose or mouth—and the swinging can still be done without obstruction or difficulty—I am, etc

Tonghai Hooper, China.

W R WELPLY

### Fibrositis

SIR—Fifty years' experience have convinced me that fibrositis is a reality not to be dispelled by scientific doubt but only by physiotherapy, and I am glad that Dr R O Adamson (Nov 27, p 956) recalls Professor Stockman's conclusive evidence in proof of its existence. Dr I H Milner (p 955) apparently agrees, but I do not quite follow him in the paragraph headed Pain.

The most common form of fibrositis affects women who do much knitting or ironing. In both these occupations the shoulder girdle is unconsciously held slightly but rigidly raised for long periods. Muscles thus maintained in contraction fail to rid themselves of the products of their own combustion, which act as irritant poisons and set up an exudative inflammation in the connective tissue. In course of time this exudation becomes organized to a greater or less degree and the 'knots' are easily felt on deep palpation. The natural movements of the arm and shoulder to ease pain stretch (but hardly tear) the muscle fibres and so tend to remove the accumulated products of muscle metabolism by improving the local circulation. Skilled massage rarely fails to relieve the condition.

Lumbago due to prolonged stooping has a similar pathology but when caused by rupture of muscle fibres is more spasmodic. That spasm of muscle *per se* causes pain can hardly be doubted by an athlete who has had the misfortune to rupture a fibre or two of his quadriceps or gastrocnemius—I am, etc

### Treatment of Abortus Fever

SIR—With reference to the article by Drs J MacD Holmes and Robert Hughes (Nov 13, p 859) on the treatment of abortus fever with sulphonamides and blood transfusions I should like to state that when I was house physician to Professor J E Debono at St Luke's Hospital, Malta, in the first six months of 1947 I saw a great number of excellent results in the treatment of undulant fever with large doses of sulphadiazine. The fever, whether of recent or late onset immediately dispersed after 3 or 4 days and did not return, though the patients were followed up for weeks afterwards. In all cases an average of 86 g of the sulphonamide was given over a period of one week; smaller doses were not successful. In recent months these good results have not been obtained, why this is so I do not know, but maybe we are dealing with different strains of the *Brucella*—I am, etc,

Floriana Malta

R O PARNIS

### Umbilical Cord Injections

SIR—In the letter on neonatal asphyxia by Mr W G Mills (Nov 27, p 956) I was interested to hear that he had experience of interference with the blood supply to the leg following an injection of nikethamide into the umbilical cord. I have reason to believe that other substances injected into the cord may owing to their entry into the umbilical artery, cause a condition similar to that described. Investigations to prove this are proceeding and will be published later—I am, etc,

Liverpool

A G O'MALLEY

### Midwives and Drugs

SIR—In your issue of Nov 27 (p 959) you publish an extract from a letter from Dr A H Driver under the title 'Midwives and Drugs'. I should like to point out to Dr Driver that in Notice No 4 of the Midwife's Code of Practice, which is published with the Rules of the Central Midwives Board it is stated that a midwife should ordinarily carry among other drugs a preparation of ergot for intramuscular injection.

Dr Driver also complains of the rigidity of the rules governing midwives. I think the only reply necessary to this complaint is to refer Dr Driver to the Rules which have been in force since October, 1947 throughout England and Wales. As far as possible the Rules have been reduced to a minimum and are largely of an administrative nature. There is added a section consisting of a number of notices which comprise a Midwife's Code of Practice. These notices are similar to the 'Warning Notices' issued by the General Medical Council for the medical profession. Their purpose is to indicate the standard of practice to which a midwife is expected to attain. In Notice No 4

already referred to, a midwife is not prevented from prescribing any drug so long as she has been "thoroughly instructed in its use and is familiar with its dosage and methods of administration or application," and so long as she observes the Dangerous Drugs Regulations.

The last point made by Dr. Driver concerns differences between the practice of different local supervising authorities. The Board is well aware of these differences which it is hoped, will disappear with the elimination since July 5 of a number of the small local supervising authorities. Although the Board cannot interfere in the normal relation of the employed midwife to the employing authority, every effort is made to encourage local supervising authorities to maintain a uniform policy in carrying out their statutory duty of supervising midwives in accordance with the rules laid down by the Central Midwives Board and the Board will be glad to take up with any local supervising authority the question of deviations from this general standard—I am, etc.,

London S W 1

ARNOLD WALKER,  
Chairman Central Midwives Board

### The M'Naghten Rules

SIR—I would like to express my general agreement with Dr. Clifford Allen's protest (Nov. 27, p. 955). The M'Naghten rules may have been good psychology in 1843, but they are now merely metaphysics and very much outmoded metaphysics by modern standards. The fact evidently needs to be impressed on our colleagues of the prison service as well as the lawyers that psychology has progressed in the past hundred years.

It is generally the psychiatrist for the prisoner who takes the trouble to investigate his past history and elicit facts that so often have an essential bearing on the dynamics of the crime. If the prison doctor has not done the same he is by so much less fully informed and is in a position to disavow any such facts on the ground that he has no direct knowledge of them. I suggest that it should be made a practice for the visiting psychiatrist to send a report of his findings to the prison doctor before the trial. It can be made clear then in court whether the prison doctor has taken the necessary trouble to confirm or refute these findings—whether, in brief, he is taking a modern attitude to the problem of crime or an 1843 attitude. Where an adequate investigation has not been made into the psychological background of a crime it simply means that at the trial the court is judging the prisoner on insufficient evidence—I am, etc.,

London W 1

FREDERICK DILLON

### Nephritis in Textile Workers

SIR—In connexion with Professor R. Platt's article on nephritis in textile workers (Nov. 15, 1947, p. 771), I wish to draw attention to certain statistical aspects which seem at variance with Professor Platt's otherwise excellent reasoning.

1. Professor Platt's argument takes as its starting point the discrepancy between the series of "Author's cases" (Table I—Deaths from Renal Disease) and the Registrar General's figures for deaths from nephritis per 100,000 at risk in each age group in the years 1930-2. As the first shows a peak for the age group 15-24 and the second a marked increase after 45 years he concludes that the latter must largely consist of deaths due to hypertension. The two series, however, are not comparable, since the first is one of deaths—or an age-case distribution—and a second one of death rates, that is the number of deaths relative to the persons at risk in each age group. The Registrar General's figures for deaths from nephritis (not rates) among females for the period 1930-2 which can be compared with Professor Platt's series, is (calculated as a yearly average)

Ages	15-24	25-34	35-44	45-54	55-64	65-69	70+
Deaths	462	276	452	1128	1917	1266	2703

From this the following facts emerge: (1) Both series show a peak in the region 16-24, and the Registrar General's thus includes deaths from renal disease proper. (2) Professor Platt's series cannot be regarded as having been obtained from a representative sample of the population at risk in each age group, since it is almost completely deficient in the higher age groups. This is confirmed if his series for deaths from malignant hypertension is considered, the trend of

which, according to Professor Platt, should be in good conformity with that of the Registrar General. As can be seen, even this series is almost completely deficient in the higher age groups, and thus shows that the population from which Professor Platt's cases were drawn did not correspond in its age composition to that of the population at large.

To draw conclusions by comparing a non-random sample with a random sample would seem a somewhat hazardous procedure in a controversial matter like the present. Strictly speaking, however, the two series are not comparable for a more obvious reason, since Professor Platt's series is one for malignant hypertension only, whereas that of the Registrar General evidently includes deaths due to benign hypertension. Had his series been one for total essential hypertension (benign and malignant) it might have shown the trend of the Registrar General's.

2. Professor Platt then compares the number of deaths from nephritis among textile workers with those of the Registrar General's social classes III and IV, with the result that he does not find a significant difference in the frequency of such deaths.

The proper background, however, against which to judge the incidence of nephritis among textile workers is not the artificial classification into social groups but the incidence in the total population of which textile workers are supposed to form a random sample. This is the procedure adopted by the Registrar General in calculating standard mortality ratios. That is, we must use the series in Table II of Professor Platt's paper as the background against which to judge the significance of deaths among textile workers as given in Table IV. Since Table II is one of death rates the data of Table IV must be transformed into rates for the purpose of comparison. We then obtain (for males) the following series with which to compare the top row of Table II:

Deaths from Nephritis per 100 000 at Risk in Each Age Group

Ages	15-24	25-34	35-44	45-54	55-64	65-69	70+
Textile Workers Deaths per 100 000	21	14	20	111	163	65	31*
All males Deaths per 100 000	15	9	18	49	108	359	189

We now see that the two series though similar in trend—since reflecting the mortality due to one and the same group of diseases—still show an increase in the death rate for textile workers in all age groups except the last. This according to Professor Platt's reasoning must be interpreted as an increased risk for dying from malignant hypertension in the higher age groups, but also as an increased risk for dying from renal disease in the lower age groups. It would thus seem—adopting Professor Platt's theory of essential hypertension as a hereditary disease for textile workers—that such workers in addition to being through their hereditary make up prone to malignant hypertension are also at an increased risk of falling a prey to renal disease through environmental factors—I am, etc.,

Bristol

G. HERDAN

### Medical Films

SIR—Mr. Malcolm Donaldson (Nov. 27, p. 955) has drawn attention to a point most worthy of consideration. In the past, considerable lip service has been paid to surgical teaching films, but who or what they teach has never been made very clear. Both in this country and in the United States medical film catalogues are studded with titles of surgical technique films. These films vary in length from a few minutes to about an hour depending very largely on whether editing has been severe or comparatively non-existent. Yet the proportion of this collection which enjoys a general distribution must be very small indeed. In searching for the reason for this it might reasonably be concluded that too many films of this type are dependent for support on the spoken commendatory of an individual surgeon or else are produced expressly to demonstrate surgical prowess.

Be this as it may, no quarrel can be sought for public money is rarely involved and, to use an actual quotation "medical film producers have to live." It is however disturbing to realize that the mere introduction of explanatory diagrams or shots made away from the tense atmosphere of the theatre may do much to clarify obscure points and can be effected without great additional expense. Footage of film alone will not teach—I am, etc.,

London S W 1

PETER HANSELL  
Director of Medical Photography  
Westminster Hospital Medical School

## H II in Malignant Disease

SIR—Regarding the case reports quoted by Mr J H Thompson and Dr G J W Ollerenshaw (Nov 6, p 835), Case 4 corresponds very closely to a patient who was under my care from 1944 to 1946. There is, however, one important detail omitted from the report—namely that his right leg was amputated through the thigh on Jan 1 1945. As this is a factor of fundamental importance in his treatment and the radiographic shadows in the chest were never proved to be metastases I think for the sake of accuracy that these facts should be stated. The account as given might lead the reader to infer that the osteosarcoma of his tibia had benefited by the treatment—I am, etc,

Bristol

R MILNES WALKER

## POINTS FROM LETTERS

## Fibrositis

Dr J B PRIMER (Aberdour Fife) writes. May I be allowed to add my testimony to the fact that fibrositis is a reality and not a chimera? As the result of an accidental wetting of the left leg I have had recurrent attacks in wet weather. Palpable nodules are now present above the left patella, and no doubt if they were examined microscopically—which heaven forbid!—they would confirm the findings of the late Professor Stoekman, of Glasgow University relative to fibrositis. But as the nodules give me no concern I leave well alone. The treatment I found efficacious was the application of iodine and methyl salicylate together with infra red therapy.

## Shortage of Nurses

Dr G D LUNG (Limpsfield Surrey) writes. It is no use building new hospitals and restoring old ones if you cannot get the staff to run them. If we cannot get enough nurses to work our hospitals and infirmaries for old people the new Health Service will break down. The reason for this shortage is that nurses especially probationers are grossly underpaid and very hard worked. The nurse is paid distinctly less than half the amount of a domestic servant and has longer hours, harder work, and less freedom. Typists shop assistants and telephone girls get much higher wages than nurses and much more freedom. Can you wonder that girls do not go in for nursing? They cannot afford to.

## Procaine Penicillin

Dr T STRATON (Fordingbridge, Hants) writes. I was interested to read the article by Drs P F Jones and R A Shooter (Nov 27, p 933) about the use of procaine penicillin. I have used it fairly extensively in general practice and found it satisfactory, though it was not possible to estimate blood concentrations. In a few cases I felt that the procaine penicillin alone was not satisfactory so in some I tried adding sodium penicillin in distilled water—200,000 units to the 300,000 units of the oily procaine penicillin. Another alternative I tried was to give penicillin and sodium citrate tablets (containing 100,000 units of penicillin) three hourly as well as the procaine penicillin. In both these methods results were satisfactory and no untoward reactions were seen. My numbers were extremely small—two in each of these groups—and so obviously do not prove anything. But I bring this to your notice in the hope that someone with the necessary facilities might consider it worth while to test the methods out scientifically. A proved satisfactory method of giving penicillin in general practice would be a great advantage.

## Sodium Sulphate for Bleeding Piles

Dr T PIRES (Weston super-Mare) writes. I was very much interested in reading of Dr Bertha Henly's experience (Nov 27, p 959) with saturated sodium sulphate solution and would therefore pick out two from several conditions with oedema and inflammation where it has proved beneficial. In the first instance I use it invariably for every slight oedema in sprains of joints though Dr Lyth's theory of how it works does not account for any effect produced through the unbroken skin. Here it is remarkable how both swelling and pain are rapidly relieved. It is best however, to continue with the dressing for a few days as this in some way ensures that the joint is not left weak and does not give way, as is so often the complaint. The other instance was the ease of a very difficult extraction of a tooth with an apical abscess. This was effected actually in two one hour sessions in the dentist's chair. In spite of local penicillin 10,000 units the cavity in the lower jaw remained unhealed and extremely painful. A prod of the saturated solution was applied for a quarter of an hour and then for three quarters of an hour. The relief from pain commenced subsequently, and at the next visit the dentist discharged the patient who nevertheless continued the applications till the gum healed over completely.

## Obituary

ARTHUR ROBINSON, M.D., LL.D. FRCS

Professor Arthur Robinson who had been living in retirement in the South of England, died at Eastbourne on Dec 3 at the age of 86. He had been professor of anatomy at Edinburgh University from 1909 to 1931.

Born in Manchester, he received his medical training at Edinburgh University where he graduated M.B. Ch.M. with honours in 1883. He at once turned his attention to anatomy and was appointed demonstrator by Sir William Turner. Two years later Arthur Robinson returned to Manchester as demonstrator in anatomy at Owens College and in 1888 he became senior demonstrator there and in due course lecturer in the Victoria University under Professor A. H. Young with whom he collaborated in several pieces of research. In 1896 Robinson was appointed the first whole time lecturer in anatomy at the Middlesex Hospital Medical School where he followed Bland Sutton. Having thus established his reputation as a rising young anatomist he moved at short intervals to the chairs of anatomy at King's College London (1900), the University of Birmingham (1904) where he was also sub-dean of the Faculty of Medicine, and finally to Edinburgh in 1909 where he succeeded D. J. Cunningham. In all these posts he displayed his talent for organization and his powers as a teacher while continuing to carry out important researches in his chosen field of comparative embryology.

Robinson's first paper 'On the Position and Peritoneal Relations of the Mammalian Ovary' appeared in the *Journal of Anatomy and Physiology* in 1887, other papers followed, and in 1890 he received a Gold Medal for his M.D. thesis on 'The Development of Two Rodents'. His best known work and that by which his reputation will stand is on the Comparative Anatomy of the Placenta embodied in three lectures which he delivered in 1903 as Hunterian Professor of the Royal College of Surgeons. As early as 1888 Robinson was collaborating with A. H. Young in morphological studies, including work on the development of the vascular system and in 1902 they were joint contributors to the first edition of the *Textbook of Anatomy* edited by D. J. Cunningham, they were responsible for the sections on general embryology and on the vascular system. Robinson himself succeeded Cunningham as editor of this well known textbook and also of the *Manual of Practical Anatomy* and was responsible for the production of several editions of each. His editorial work no doubt took up a great deal of his time, but he continued to pursue the developmental problems that interested him. He did further work on the formation of the ovarian follicle, the presence of lipoids in mammalian ova and the development of veins—the last a subject on which he was recognized as a great authority.

From 1920 to 1922 Professor Robinson served as president of the Anatomical Society of Great Britain and Ireland which he had joined in 1889. In 1920 he was Struthers Lecturer of the Royal College of Surgeons of Edinburgh, of which he became a fellow in 1912 and took as his subject 'Prenatal Death'. In 1924 he was elected FRCS, and the Royal Society of Edinburgh awarded him the Neill Prize for the period 1925–7 for his Contributions to Comparative Anatomy and Embryology. He was a Fellow of King's College London and he received the LL.D. from the University of Edinburgh on his retirement. Professor Robinson's preparations for retirement in 1931 were clouded by serious eye trouble which gave rise to much anxiety. But his friends were relieved to learn that a good measure of sight had been spared to him. His resilient spirit enabled him to overcome the disability that remained and in these later years of his long life he quietly enjoyed the general reading for which during his very active professional days he had always regretted that he had so little time.

Professor Robinson married Emily, third daughter of John Bailly in 1888 and in this year of their diamond anniversary we extend our sympathy to Mrs. Robinson on the loss she has sustained.

## F B PARSONS, M.D., F.R.C.P.

Dr Frank Bett Parsons was at work and in full vigour until within a few days of his untimely death, at the age of 46, on Dec 4 after a very short illness.

He was born at Chatteris Cambridgeshire, and from Welham borough he entered Downing College, and again returned to Cambridge after qualifying in 1925 at St Bartholomew's Hospital. He took the Cambridge M.B. in 1926, and proceeded M.D. in 1929, his thesis embodying work on the action of drugs, much of which was carried out under the late Professor W. E. Dixon in the pharmacological laboratory. A few years in general practice, one at Guildford preceded his entry into consulting medicine on his appointment to the staff of Addenbrookes Hospital in 1938. But Parsons had managed to keep in touch with the pharmacological aspects of medicine, and he published papers on 'avertin', on anaesthesia and on mechanical laxatives. Parsons had an original mind and the faculty of an alert curiosity which made him seek out things for himself never content to accept a fact or theory simply because it had the weight of authority behind it. His energy and ability soon brought their reward in other appointments, notably as honorary physician to Papworth Village Settlement and as liaison officer between the hospital and the university, a new departure which foreshadowed the closer and happier linkage which now exists. He was elected a fellow of the Royal College of Physicians in 1946.

Dr Parsons was a keen and active member of the Cambridge Medical Society and of the B.M.A. and was secretary of the local Cambridgeshire and Huntingdonshire Branch for several years. He was also vice-president of the Section of Neurology at the Annual Meeting in Cambridge only last July. Though neurology had become increasingly his specialty, he remained always a general physician. As a successful consulting physician in a big rural area he found the demands on his time and energy left no leisure for other pursuits, and medicine was in a sense his great hobby. Parsons had a gentle manner which came of his personal modesty and kindness, and his services were always available to his colleagues and a large circle of general practitioners in country and town who had grown to rely on his willingness, sound judgment and even temper. He was interested in people and had a retentive memory for details of family and face, and no doubt this was one clue to the great esteem and affection in which he was held. But he was also a fighter, and nothing roused him to action more certainly than the bureaucratic touch. In it he saw the interests of patient and doctor alike threatened, or forgotten. All who knew him and they are many will feel his loss deeply. No one can quite fill his place in the community, and the sympathy of his colleagues and friends will be extended to his widow and two children.

S. H. P. writes: Ten days before his untimely death Frank Parsons told me that he was a sick man. With a full realization of the inevitable outcome of his illness he put his affairs in order and waited calmly and with fortitude. Parsons will long be remembered in Cambridgeshire, his own county. His loyalty to his colleagues was absolute, his kindness to patients proverbial. As a consultant he never lost sight of the difficulties and problems of the general practitioner, and his advice, always helpful and greatly sought, was invariably tempered with sound common sense. We all deplore the loss of a good friend.

A former pupil writes: Dr Parsons's short illness and early death will come as a tragic blow to his hosts of friends, both medical and lay. He held a unique position as consulting physician in Cambridge and for fifty miles around. He had a prodigious memory for people and places and was a man of fearless independent thought, like Hughlings Jackson and Sir James Collier, whom he often quoted. He had an intimate knowledge of neurology and pharmacology, but his students learnt most from his philosophy of life and from his perfect handling of his patients and their relatives. His students of many generations will sorely miss him.

Dr RICHARD VINCENT BREWS died in the London Hospital at the age of 75 on Oct 28. After qualifying at the Royal College of Surgeons, Dublin, in 1898 he took up practice in North

Woolwich, and had worked there ever since until six weeks before his death. Dr Brews had been a member of the B.M.A. for the past thirty seven years and took a leading part in all local medical matters. He was a member of both the East Ham Panel Committee and the East Ham Insurance Committee from their constitution in 1921 until 1948. He was made chairman of the Panel Committee in succession to the first holder of that office, Mr J. W. Hill, and was elected chairman of the Insurance Committee in 1937. His tact and ability, allied to his thorough knowledge of the National Health Insurance Act made him an invaluable member of both committees and earned for him the admiration of both his medical and lay colleagues. He served as police surgeon to the 'K' Division of the Metropolitan Police for over fifty years, and was a justice of the peace for the County of London. When the blitz came Dr Brews had reached retiring age. Rather than retire he stayed to face its dangers and its rigours. In 1943 he was attacked by a grave illness, but he carried on his work while under treatment and fought his way to complete recovery. His courage and fortitude in these hard years were a shining example to the neighbourhood. Dr Brews had a cultured mind, a clever pair of hands, and an immense capacity for work. He was receptive of new ideas to the end and kept abreast of all advances in medicine. If there were an hour or two of leisure in the day he retired into his little workshop to amuse himself at woodwork or in mending machinery. His other hobbies were fishing and shooting. He leaves a son, Alan, who is gynaecologist to the London Hospital, and a daughter, Mrs Barlow, who has exhibited paintings at the Royal Academy. His patients, long used to an ideal blend of kindness and firmness will miss him sadly, so, too will his friends his medical colleagues and all who knew him.

## Medical Notes in Parliament

The Dangerous Drugs Regulations, 1948 and the Raw Opium Regulations, 1948, were presented to Parliament on Dec 8.

### National Service

Speaking on Dec 6 during the Committee stage of the National Service Bill, Mr A. V. ALEXANDER said young men liable for whole time service for eighteen months after Jan 1 would be able as at present to apply for deferment to complete their studies before call-up. Their application would generally be granted. If they chose to do their military service first they could ask to be called up early so as to be out in time to go to the university in the appropriate October at the beginning of the university year. Later in the same debate Mr ISAACS said that normally there was about three months between announcement of a registration and earliest call up.

Mr HUGHES pointed out that in the United Kingdom in 1946 cases of venereal disease were 7.7 per 1,000 strength. In the B.A.O.R. the proportion rose to 30.4 for the first quarter 41.8 for the second quarter 44.6 for the third quarter and 41.8 for the fourth quarter.

Mr EMERY HUGHES quoted an estimate in a Free Church Council report that 80% of the Army personnel on the Continent was supplied with prophylactics.

Mr SHINWELL said that, provided proper care was taken of the welfare of young soldiers in Germany and that they were engaged in arduous military training, they were all right.

### Ceiling for Dentists

Replying on Dec 9 to Mr MCGHEE, Mr BEVAN declared that he was undertaking with the dental associations a full review of the present translation of the Spens Committee into fees for services. Meanwhile as it was obvious that some dentists earned far more than that Committee ever contemplated he was adopting a temporary arrangement whereby fees were reduced by half after a dentist reached an income of £4,800 gross—or £1,000 in excess of the point at which the Spens Committee said the risk of bad dentistry began. Mr Bevan recalled that doctors already had a limit in the number of patients allowed on their lists.

Mr BESWICK on Dec 9 asked Mr Bevan, in view of the grave shortage of dental practitioners, to see that the services of qualified dental practitioners who came to this country before 1939 were fully utilized.

Mr BEVAN said that the admission of foreign-trained dentists to the *Dentists' Register* was under statute a matter entirely for the General Medical Council.

On the same date Dr SARGAL asked how many dentists with foreign qualifications had been refused registration in this

country Mr BEVAN said there were approximately 1,200 such cases since 1935 (inclusive) when foreign dentists began to enter this country from the Continent in appreciable numbers. He explained that the Minister of Education had no objection to the employment in the School Dental Service of any foreign dentists provided that they were legally entitled to practise dentistry in this country.

Mr BEVAN further explained that the conditions on which foreign trained dentists could practise in this country were prescribed by the Dentists' Acts. The duty of ensuring that these conditions were fulfilled rested with the General Medical Council.

In reply to a further question Mr BEVAN said that of the sum of £4 750 000 paid or owing to dentists for work completed under the National Health Service up to about 40% was in respect of new dentures.

#### If and When

On Dec 9 Mr JOYNSON-HICKS inquired whether Mr BEVAN knew that medical specialists were, under the operation of the National Health Scheme, limited to making a total of twenty-five visits per quarter upon patients in a given area.

Mr BEVAN replied that there was no limit on visits. Remuneration had a provisional ceiling for each quarter while longer-term arrangements—which would date back—were being worked out. The question of treatment of patients when a specialist had filled his schedule would be considered if and when it arose.

#### Dr Voeller's Claims

Dr SEGAL asked on Dec 9 how many British subjects had been enabled to travel to Kassel to undergo the Voeller treatment for Parkinson's disease.

Mr BEVAN said that no British subjects had so far been permitted by the United States authorities to travel to Germany for treatment by Dr Voeller. He was arranging a full investigation into Dr Voeller's claims. If these were substantiated he would see what could be done to ensure that the treatment was available to all sufferers from the disease.

## Medico-Legal

### NULLITY AFTER ARTIFICIAL INSEMINATION

[FROM OUR MEDICO LEGAL CORRESPONDENT]

In the nullity suit *R E L v E L* tried before Mr Justice Pearce in the Divorce Division on Nov 30 it appeared that the parties were married in 1942, the wife being 25 and the husband 31. For the first three years the husband made no attempt to consummate the marriage saying that it was difficult to have children during the war. He also found it difficult to talk about sex. In June, 1945 the wife made him face the question, and he was never able to consummate the marriage. In the autumn of that year the wife consulted a doctor for bad health and nervous trouble. The doctor impressed the seriousness of the position on the husband and tried to persuade him to undergo psychotherapy but the husband was unwilling. The wife was anxious to have a child and discussed artificial insemination with him. At the end of 1946, under expert guidance she tried to inseminate herself with the husband's semen but failed. In December, 1947, the husband visited a psychologist at whose suggestion the wife had an artificial insemination from the husband. At the end of January she decided to leave him, not knowing she was pregnant, and a child was born in September. She petitioned the court for a decree of nullity on the ground of the husband's incapacity to consummate the marriage. The husband did not contest this allegation, but pleaded that by accepting artificial insemination his wife had approbated the marriage and that to grant a decree of nullity and thus make the child illegitimate would be against the public interest.

Mr Justice Pearce said in his judgment that the cause of the husband's incapacity seemed to be a deep seated neurosis. The wife was a perfectly honest woman who had tried hard to make a success of the marriage under difficulties that involved considerable strain and humiliation. The marriage had broken down hopelessly and she could never go back to it. There had just been a chance that the birth of a child might have

overcome the husband's psychological trouble or have resigned the wife to an unnatural marriage. There was no lack of sincerity on her part: she had not willingly acquiesced in an impotent marriage. He saw no hope of happiness from keeping the couple married. The future held better augury for the child if he granted a decree than if it were brought up by an embittered wife, tied up for life to a marriage that had never been a real marriage. That the child should be made illegitimate was most regrettable but sons were not now judged by the errors of their parents. The few who would know of the illegitimacy would probably also know the facts and there was nothing that reflected any dishonour on either of the parents or the child. He therefore granted a decree of nullity.

The question of the illegitimacy of such a child is new for without artificial insemination a child cannot be born if the husband is impotent. It should be carefully noted that the learned judge did not decide, and indeed had no power to decide, that this child was illegitimate. All he did was to state that in his opinion the effect of his decree was to render the child illegitimate. As one legal correspondent pointed out, this does not imply that a child conceived by artificial insemination is illegitimate if the marriage is valid. Moreover, it is by no means certain that the judge is right. Another legal opinion was that the child was born of parents who had gone through the marriage ceremony and were entitled to go through it, and that it therefore could not be illegitimate. According to the same source, the mother's solicitors point out that, assuming she has already obtained a birth certificate giving the name of the husband as father, the certificate will remain showing the child as legitimate. She has given no wrong information. The Ministry of Health is quoted as saying that a correction to a birth certificate is made only where false information has been given in the first place, and the Registrar General as saying that the case has no precedent and that the information was apparently correct at the time it was given. The court could be moved for a declaration of legitimacy on behalf of the child but not—except in the course of some other matter such as a claim to succession to property—for a declaration of illegitimacy, and the present decree of nullity does not operate as such a declaration.

There is as yet no legislation on artificial insemination, but the law contains an interesting analogy within the provision allowing a marriage to be annulled for wilful refusal of one of the parties to consummate it. This is a new ground, introduced by Herbert's Act in 1937, and of course it brought as its consequence the possibility that a marriage might be annulled even though a child had been conceived before the parents had married and had been rendered legitimate by their marriage. To protect such a child from being made illegitimate again by the nullity, Parliament expressly enacted in Herbert's Act that the decree should not have that effect. Undoubtedly in justice the same principle should operate here, and perhaps such provision will be made if and when Parliament is called upon to legislate for artificial insemination. Meanwhile, with due respect to the learned judge, the question of the child's legitimacy remains open.

In the House of Commons on Dec 7 Mr Driberg asked the Prime Minister if he would consider the appointment of a Royal Commission to examine the social and legal implications of the practice of human artificial insemination, including A.I.D., with special reference to the problems of legitimacy and inheritance involved. Mr Attlee replied that he would prefer first to see the general Report of the Royal Commission on Population which was said to be in the final stages of drafting. It seems clear from the statement of the Prime Minister and a previous statement given on behalf of the Attorney-General that any question of legislation on the subject of artificial insemination will have to await the appearance of the long-awaited Report of the Royal Commission on Population. On the other hand Mr Ede announced on Dec 9 that in consultation with the Attorney-General he was considering the introduction of a Bill to legitimize the children of parents who had gone through a marriage which was later annulled.

*Introducing*

**NUTRITION . . .**

*the answer to modern  
 dietary problems*

There is evidence that the reduced daily calorie intake of the nation, resultant upon the lower quantitative and qualitative food standards of to day, has a tendency to be a contributory cause of asthenia.

The physician rightly seeks a corrective for this condition, especially in patients where an examination reveals nervous instability, lassitude and weakness arising from a deficiency of vitamins and mineral constituents.

Supavite 'Capsules, by providing a balanced ration of vital food factors—vitamins A, B<sub>1</sub>, B (G), C, D and E, together with Iron, Calcium and Phosphorus, enrich the depleted tissues and fluids and encourage the restoration of bodily health.

**FORMULA**

Each AMBER capsule contains	Each ELACK capsule contains

**'ESTIGYN'**

(Ethinyl Oestradiol B.D.H.)

*An Orally Active Derivative  
 of the Natural Oestrogen, Oestradiol*

Ethinyl oestradiol is unique in that it is a simple derivative of the natural ovarian hormone which is highly active when administered orally. It is now available for clinical use as 'Estigyn'.

'Estigyn' may be prescribed in all cases in which an oral oestrogen is indicated, especially those in which the physician hesitates to prescribe one of the synthetic, non steroid oestrogens.

Toxic reactions, such as headache, nausea and vomiting, are rare following the administration of 'Estigyn' and are most unlikely after the usual therapeutic doses.

'Estigyn' is issued in tablets containing 0.05 mg. each tablet scored for convenience in giving, doses of 0.025 mg. when these are required.

Literature is available on request.

## The simple answer to this global problem

Whatever the form of macrocytic anaemia, Examen liver extract reduces treatment to the simplest possible terms. Highly refined and concentrated Examen is fully effective in small injections—with consequent benefits both in convenience and economy—appreciated by patient and doctor alike.

Preliminary enzyme digestion of the raw liver ensures that the liver cell structure is broken down. The anti-anaemic factor is thus freed from its combination with protein and becomes to all available in Examen. This important advance in manufacturing technique also lessens still further the risk of sensitization to liver.

Examen has not only specific action but its effective stimulation of the haemopoietic system is of considerable value in many of the chronic infections met with in warm climates.

GLAXO  
**EXAMEN**

Injectable Liver Extract

Ampoules 3 x 1 cc and 6 x 1 cc

Bottles 5 cc & 5 x 5 cc

Available throughout the world—

## The Easy Way

TO INVEST  
MONEY

Buy National Savings Certificates the Bank way—it is simple, automatic and without any additional charge to you. You just sign the special Banker's Order form which your Bank Manager can now give you, authorising either a single purchase of National Savings Certificates, or a regular monthly investment. That is all you have to do—and with a stroke of the pen you will have helped to secure your own future, and your country's prosperity.

You can now hold 1 000 10/- units of the new Certificate, and in ten years this £500 will have grown to £650 free of tax. Secure for yourself this profitable gilt-edged investment by calling on your Bank Manager.

## SAVE—The Bank Way

Issued by the National Savings Committee

## The heart that is ageing

In these days when increasing attention is being devoted to the care of the elderly, the use of certain xanthine derivatives has gained considerable favour for improving myocardial function and for patients whose coronaries are probably sclerotic or constricted. A useful representative of this group for routine treatment may be found in

## Cardophylin

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov 27

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1948					1947 (Corresponding Week)

† Deaths from measles and scarlet fever for England and Wales London (administrative county) will no longer be published

‡ Includes primary form for England and Wales London (administrative county) and Northern Ireland

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales London (administrative county) are combined

|| Includes puerperal fever for England and Wales and Eire

## EPIDEMIOLOGICAL NOTES

## Tuberculosis in the British Zone

According to the *Monthly Report* of the Control Commission for Germany, the death rates in the British Zone from pulmonary tuberculosis during the first six months of 1948 were less than those for the first half of 1947. These rates, calculated as annual rates per 10 000 of the population were 6.54 and 6.8 in 1948 and 1947 respectively. It is two years since a large increase in the incidence of the disease was first reported, but the number of deaths has actually decreased despite the arrival in the British Zone of a great many refugees and prisoners of war from the east suffering from advanced tuberculosis. This bears out the findings of the British Medical Research Council on tuberculosis in the British Zone—namely, that the increase reported by German doctors was a paper increase only, resulting from a revised scheme of reporting. The number of deaths from other forms of tuberculosis has also decreased. The annual rates per 10 000 of the population were 1.36 in 1948 compared with 1.7 in 1947.

The annual death rate for pulmonary tuberculosis in the British Sector of Berlin during the first half of 1948 was 12.7 per 10 000 of population compared with 18.3 for the similar period in 1947. With regard to other forms of tuberculosis there was no change in the number of deaths which remained at 1.4 per 10 000 per annum for the first half of 1947 and 1948. In Berlin as a whole the death rate for tuberculosis is higher than in the British Sector, and although there has been a decrease during the past two years it is still higher than the rate in the British Zone.

## Discussion of Table

In England and Wales increases were recorded in the notifications of measles 1,624 whooping cough 67 and dysentery 23, and decreases for scarlet fever 291, acute pneumonia 16 and diphtheria 13.

The rise in the incidence of measles was mainly concentrated in the north, and only a slight increase occurred in the southern section of the country. The largest rises were Lancashire 492, Yorkshire West Riding 233, Lincolnshire 173, Derbyshire 142, and Staffordshire 104. Only small changes were recorded in the returns of whooping cough, the largest were a rise of 42 in Cheshire and of 43 in Devonshire.

A decreased incidence of scarlet fever was recorded throughout the country, the largest falls were Lancashire 60, Yorkshire West Riding 46, Middlesex 35, and Staffordshire 23.

In contrast to the general trend of diphtheria a rise of 11 was recorded in Lancashire partly due to an outbreak affecting 7 persons in Standish with Linnetree UD. Another local outbreak of diphtheria was in Glamorganshire Merthyr Tydfil CB 8. The largest variation in the local returns of acute pneumonia was a decrease of 27 in Lancashire.

An outbreak of dysentery affecting 14 persons was notified in Glamorganshire, Pontardawe RD. Other returns of dysentery were Lancashire 13, Essex 10, and London 9. The largest returns of acute poliomyelitis were Lancashire 4, Warwickshire 4, and Middlesex 3.

In Scotland increases occurred in the notifications of measles, 44, acute primary pneumonia 18 and whooping cough 10, and there were decreases in diphtheria 21 and scarlet fever 44. Notifications of diphtheria in the city of Glasgow fell from 31 to 14. There were 8 fewer cases of dysentery notified from Glasgow, but an outbreak affecting 6 persons was notified in Greenock.

In Eire decreases were recorded in the notifications of measles 16, whooping cough 16, scarlet fever 9, and diphtheria 7. An outbreak of whooping-cough with 11 notifications occurred in Tipperary, Nenagh RD.

In Northern Ireland an increase of 14 was reported in the notifications of scarlet fever. Notifications of measles from Belfast CB were 12 in excess of the total of the preceding week.

## Quarterly Returns for Scotland

The birth rate during the third quarter was 18.7 and was 0.1 below the average of the five preceding September quarters. The infant mortality was 40 per 1 000 registered live births and was 12 below the five years' average. Stillbirths were equivalent to a rate of 28 per 1 000 total births. The general death rate was 10.5 per 1 000 and was 0.1 below the five years' average. The death rate from all forms of tuberculosis was 66 per 100 000 and that from respiratory tuberculosis was 59. These rates were respectively 3 below and 6 above the average rates for the third quarters of the five preceding years. Only 51 deaths were attributed to the principal epidemic diseases.

and the rate was only half of the five years average. These deaths included 17 from whooping cough, 16 from influenza, 8 from diphtheria, and 6 from cerebrospinal fever.

#### Week Ending December 4

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,527, whooping cough 2,562, diphtheria 131, measles 8,562, acute pneumonia 897, cerebrospinal fever 33, acute poliomyelitis 51, dysentery 64, paratyphoid 10, and typhoid 4.

## Medical News

#### Vice Chancellor of Hong Kong University

Colonel Lindsay Tasma Rida has been appointed Vice Chancellor of the University of Hong Kong.

An Australian Rhodes scholar, Colonel Rida graduated in medicine at Oxford University in 1927 after receiving his clinical training at Guy's and proceeded D.M. in 1939. He has been professor of physiology at the University of Hong Kong since 1928.

#### Thomas Percy Legg Memorial Lecture

The first Thomas Percy Legg Memorial Lecture entitled 'Principles of Surgery Exemplified in the Story of Hare Lip and Cleft Palate' was delivered by Mr Denis Browne on Dec 3. The lecture was founded this year in memory of Thomas Percy Legg, C.M.G., M.S., F.R.C.S., surgeon to King's College Hospital from 1910 to 1930, and is given annually on a surgical subject on the invitation of the Council of King's College Hospital Medical School.

#### Gastroenterological Prize

The National Gastroenterological Association will award \$100 and a certificate of merit for the best unpublished contribution on gastroenterology or allied subjects. Certificates will also be awarded to those physicians whose contributions are deemed worthy. Contestants residing in the United States must be members of the American Medical Association, those residing in foreign countries must be members of a similar organization in their own country. The winning contribution will be selected by a board of judges, and the award is to be made at the Annual Convention Banquet of the National Gastroenterological Association in October of 1949. The Association reserves the exclusive right of publishing the winning contribution and those receiving certificates of merit in the *Review of Gastroenterology*. All entries should be limited to 5,000 words, be type written in English, prepared in manuscript form submitted in five copies accompanied by an entry letter, and must be received not later than April 1, 1949. They should be addressed to the National Gastroenterological Association, 1819, Broadway, New York, 23, N.Y.

#### Postgraduate Training in Psychiatry

The South West Metropolitan Regional Hospital Board, with the requirements of the English Conjoint D.P.M. in mind, is preparing a training course in psychiatry on lines not hitherto attempted in this country. Every six months six registrars will be accepted for training in the Board's hospitals and each of them will pass through three hospitals over a period of two years. During the first phase of nine months two trainees will go to each of three hospitals close to London and to each other. At Belmont (Sutton) Hospital clinical material is largely psychoneurotic and there is a substantial industrial unit and a department of electroencephalography. At St Ebba's Hospital early psychotic cases are admitted and plans are complete for the establishment of departments of electroencephalography and neuropathology. Netherne is a progressive modern hospital, having special emphasis on clinical research. These three hospitals will pool resources so that wherever the trainee is sent he will have an opportunity of studying the work of all three. The staff of the teaching hospitals will participate in formal teaching and the necessary instruction in neurology will be completed before passing on to the second phase.

Graysnevel Hospital, St James Hospital, Portsmouth, and Warrlingham Park Hospital will provide the training for the second period of nine months. These hospitals offer comprehensive mental health services with a wide range of community contact. At this phase a measure of clinical responsibility will be undertaken under supervision and the trainee will fit into the general framework of the hospital staff so far as possible. Tuition in child psychiatry visits to courts, prisons and approved schools, and practical experience of community services will be arranged during this period. The last six months before taking the D.P.M. will be spent in a mental deficiency institution—the Fountain Hospital, Botleys Park and the Manor. For the first year a salary of £700 will be offered, with an increase to £800 during the second year. Experience in a general hospital will be obligatory and preference will be shown to those who have had six months experience in mental hospitals as house-physicians and who have decided to specialize in psychiatry.

#### Training for Ward Sisters

King Edward's Hospital Fund is about to open a staff college in South Kensington to which State registered nurses may come for short courses in preparation for ward sisters posts. If the experiment is successful it is hoped that it will be followed elsewhere. The staff college is under the general guidance of a committee of the Fund, and a principal, warden, and other staff have been appointed. The courses will be of four months duration and will be open in the first instance to nurses seconded for the purpose by hospital management committees and boards of governors in the four metropolitan regions. The first will be held early in 1949, and subsequent courses will be at four monthly intervals. There are no fees and the cost of tuition and residence is being defrayed by the King's Fund. The scheme has the full support and active interest of the Ministry of Health. Inquiries should be addressed to the Secretary, Nursing Recruitment Service, King Edward's Hospital Fund, 21 Cavendish Square, London, W.1.

#### British Council Scholarships

Some 60 British Council scholarships out of a total of 359 new awards and extensions for the academic year 1948-9 have been awarded to scholars studying medical subjects. The scholarships are awarded to overseas graduates or others of like status to enable them to undertake a year's specialist study at a British University, college, hospital, or other educational institution.

#### New Haematological Journal

*Acta Haematologica* is a new journal published in Switzerland by S. Karger, of Basle. It prints articles in English, French, and German, each with a summary in all three languages. The English editor is Dr F. Rosenthal, of Leicester. The journal will publish original articles on haematology as well as surveys of the specialty and book reviews.

#### Medical Golf

At the annual general meeting of the London Irish Medical Golfing Society held on Nov 18 Dr J. E. Ambrose was elected president and Dr S. C. Morrow captain for the year 1949.

#### National Service

The Ministry of Labour reports that 299,121 medical examinations were carried out in 1947 on men and women volunteering or called up for National Service. 117 men were prosecuted for refusing to submit to medical examination. The Nursing Appointments Offices placed 10,534 men and women in whole time nursing posts and 2,446 in part time nursing posts. At the end of the year there were 2,488 vacancies for men and 29,622 for women. At the middle of December, 1947, there were 846,000 disabled persons voluntarily registered under the Act of 1944, most of them were in employment. During the year 6,822 disabled men and women completed vocational training courses.

#### Willis

Professor Daniel Dougal, of Manchester, left £31,312. He left his microscope and all medical books to the Victoria University Manchester, for the use of the department of obstetrics. Dr Kenneth William Mackie of Salisbury Green Hants, left £11,281. Mr William Dawson Galloway, of Huddersfield left £15,028 and Dr John Alexander Watt, of West Runton, Norfolk left £13,666. Dr Watt bequeathed £200 to Aberdeen University in appreciation of the scholarship awarded to him when a student for a medal or prize in preventive medicine.

## COMING EVENTS

#### Health Education

The Ling Physical Education Association will hold a conference on 'Health Education in Schools' from Dec 29, 1948 to Jan 1, 1949 at Chelsea Polytechnic, Manresa Road, London SW3. It is open to members of the Ling Association and of the Association of Women Science Teachers. Information may be obtained from the Ling Physical Education Association, Hamilton House, Bidborough Street, London, W.C.1.

#### Congress of Otolaryngology

The 4th International Congress of Otolaryngology will be held in London on July 18-23, 1949. Those wishing to attend the congress should apply not later than March 1, 1949, to the secretary, International Congress of Otolaryngology, 45, Lincoln's Inn Fields, London, W.C.2.

#### International Veterinary Congress

The 14th International Veterinary Congress will be held at Central Hall and Church House, Westminster on Aug 8-13, 1949. The programme will be issued later. Information may be obtained from the organizing secretary, 10, Red Lion Square, London W.C.1.

## SOCIETIES AND LECTURES

## Monday

HUNTERIAN SOCIETY—At Talbot Restaurant, 64, London Wall E.C., Dec 20, 7 for 7.30 p.m., dinner 8.30 p.m., discussion 'Toxic Jaundice' to be opened by Professor John McMichael and Dr Alice M. Stewart

## Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Edinburgh Royal Infirmary (West Medical Lecture Theatre), Dec 21, 5 p.m. 'Nutrition in Europe During the War and After' by Dr A. P. Meiklejohn

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Dec 21, 5 p.m. 'Cutaneous Reticuloendothelioses' by Dr F. R. Bettley

INSTITUTE OF UROLOGY—At St. Paul's Hospital, Endell Street, London, W.C., Dec 21, 11 a.m. 'Aetiology and Diagnosis of Gonorrhoea' by Dr W. N. Mascall

## Wednesday

INSTITUTE OF UROLOGY—At St. Paul's Hospital, Endell Street, London, W.C., Dec 22, 11 a.m. 'Pathology of Gonorrhoea' by Dr A. H. Harkness

## Thursday

INSTITUTE OF UROLOGY—At St. Paul's Hospital, Endell Street, London, W.C., Dec 23, 11 a.m. 'Signs, Symptoms and Asymptomatic Carrier State of Gonorrhoea' by Dr A. H. Harkness

## APPOINTMENTS

Dr S. L. A. Manuwa has been appointed Deputy Director of Medical Services in Nigeria

BURNETT J. S. G. M.D. D.P.H. Medical Officer of Health Preston  
CARTER LOCKE H. B. C. M.B. B.S. D.P.H. Deputy Medical Officer of Health Bromley Kent  
FREEMAN P. M.B. Ch.B. D.P.H. Deputy Medical Officer of Health Cheltenham  
KAHN J. H. M.D. D.P.M. Psychiatrist Child Guidance Clinic Huddersfield  
LAWRENCE I. B. M.B. Ch.B. D.P.H. Assistant Medical Officer for Dorset and Medical Officer of Health Portland  
MEYON U. K. M.B. B.S. D.T.M. Resident Medical Officer Oakwood Hall Sanatorium Rotherham  
NEVIN MARY E. M.D. D.P.H. D.C.H. Medical Officer North London Region, Ministry of Pensions  
ROBINSON MARGARET M. F. M.D. D.P.H. School Medical Officer Kettering  
RONALD JAMES M.D. F.R.C.P. Ed. Consultant Physician Scottish Northern Regional Hospital Board  
TAYLOR G. H. M.D. D.P.H. Deputy County Medical Officer of Health and Deputy School Medical Officer, Warwickshire

## BIRTHS, MARRIAGES, AND DEATHS

## BIRTHS

Franklin.—On Dec 8 1948 to Margaret wife of Dr C. B. Franklin a son Tighe.—On Nov 30 1948 at Queen Elizabeth Hospital Birmingham to Nora (née Cressan) S.R.N. S.C.M. wife of Dr Robert Tighe of 101 Ashsted Row Birmingham a daughter—Maureen Elizabeth

## MARRIAGES

Griffiths—Meigh.—On Nov 6 1948 at St James's Church Bradford Alan Lampen Griffiths M.B. B.Ch. B.A.O. D.C.H. of Larnie to Gladys Audrey Meigh B.A. M.B. Ch.B. D.C.H. of Bradford  
Mumford—Mackenzie.—On Nov 27 1948 at St John the Evangelist's Church Blackheath Wilfred Bardwell son of Mr and Mrs E. B. Mumford of Boscombe to Ruth younger daughter of Mr and Mrs J. A. Mackenzie of Blackheath

## DEATHS

Blayney.—On Dec 4 1948 at 31 Tudor Drive Watford William Blayney M.R.C.S. L.R.C.P.  
Bradley.—On Dec 3 1948 at Greville House Raynes Park Wimbledon S.W. James Edmund Campbell Bradley M.B. B.Ch. aged 84  
Callender.—On Dec 2 1948 as the result of a cycling accident Constance Muriel Callender O.B.E. L.R.C.P. & S. Ed. L.R.F.P.S. Glas. of Kingsdown Deal late of Mima Egypt  
Davis.—On Dec 2 1948 at White Lodge Sonning-on-Thames John James Davis M.R.C.S. L.R.C.P. aged 43  
Dunbridge.—On Dec 3 1948 at Newport Pagnell Henry Dunbridge M.R.C.S. L.R.C.P. formerly of Matlock Derbyshire aged 77  
Henderson.—On Dec 1 1948 at 83 Hepburn Gardens St Andrews Fife George Edward Walker Henderson L.R.C.P. & S. Ed. L.R.F.P.S. Glas.  
Horsley.—On Dec 2 1948 at Hackney Hospital London E. Lancelot Horsley M.R.C.S. L.R.C.P. of 27 Gloucester Place London W.  
McKenna.—On Dec 2 1948 at Greystones Nursing Home Prestwick Fergus McKenna M.B. Ch.B. Glas. of Doune Alloway Ayr  
Stewart.—On Dec 4 1948 in a London Hospital Sir Edward Stewart K.B.E. M.D. of Bullards East Grinstead Sussex, late vice-chairman B.R.C.S. aged 91  
Turner.—On Dec 9 1948 James William Turner M.R.C.S. L.R.C.P.  
Wilson.—On Nov 30 1948 at Linton Cambridge Hugh Mundle Wilson M.B. Ch.B. Glas. aged 63

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

## Vitamin B Supplements

Q—There seems to be an increasing tendency to consider that children of 1 to 5 years are not adequately fed unless their normal diet is supplemented by proprietary preparations containing vitamins. Taking the vitamin-B group could you please advise on the following points: (1) Is any reliable information available regarding the needs of normal children aged between 1 and 5? (2) Is there adequate evidence that such children run any risk under present conditions of vitamin-B shortage? (3) Is there evidence that a child already receiving an adequate amount of vitamin B in a normal mixed diet derives benefit from additional intake of vitamin B (apart of course, from the few additional calories)?

A—(1) The 'Recommended Dietary Allowances' published by the Food and Nutrition Board of the National Research Council, U.S.A. (Washington, D.C., revised 1945), include the following figures

	Vitamin B <sub>1</sub>	Riboflavin	Nicotinic Acid
	mg	mg	mg
Children aged 1 to 3	0.6	0.9	6
4 to 6	0.8	1.2	8

The League of Nations "Report on Vitamin Requirements" (*Bull. Hlth. Org. L.N.* 1938, 7, 460) gives 200 to 250 i.u. (=0.6 to 0.75 mg) of vitamin B<sub>1</sub> per day as the amount "probably sufficient for nursery-school children." This is in good agreement with the American estimate. The other vitamins of the B group are not considered individually in the League of Nations report. It is worth noting that the American figures are 'recommended allowances' and not 'minimum requirements'—that is, they appear to allow an ample margin for safety as well as for individual variation. In any case the reputed requirements of these B vitamins of young children of 1 to 5 were based more on broad estimates than on any precise determinations.

(2) Little work has been published in Britain about the vitamin intakes of children between 1 and 5 years old. In a recent survey Bransby and Magee (*British Medical Journal* 1947, 1, 525) estimated the average intakes of vitamin B<sub>1</sub> derived from rations and allowances to be as follows

Children of 1 year	mg
2 to 3 years	0.77
4 years	0.74
	0.92

Children of 1 to 5, according to these authors, actually had on the whole a better provision of most nutrients than had almost any other age. In fact, other groups of the population were thought to make up any relative deficiencies from out of the "family pool"—that is, from the "surplus" allowed to children between 1 and 5.

(3) Of course, if it be accepted that the normal mixed diet is already adequate, obviously no advantage is to be expected from increasing the intake by the use of supplements. It must be admitted that, so far as Great Britain is concerned, there have been few if any direct scientific data on the possible benefit to health of supplements rich in B vitamins for normal children of 1 to 5 years. In America, however, groups of under-weight children, tuberculous children, and others have sometimes been found to benefit when given extra vitamin B in the form of wheat germ, cereal preparations, yeast, or vitamin-B concentrates (Summerfeldt, *Amer. J. Dis. Child.* 1932, 43, 284; Ross and Summerfeldt, *ibid.*, 1935, 49, 485; Joslin and Helms, *Arch. Pediat.* 1937, 54, 533). Similar claims have been made for

infants and sometimes for adults (for literature see Harris, *Vitamins and Vitamin Deficiencies* 1, 71). More recently Harrell also in America (*J Nutrit* 1946, 31 283) claimed improvement in 'mental and physical skills' in school-children given extra vitamin B.

In this country the substitution of wheatmeal flour and the national loaf for the formerly current white flour and white bread has undoubtedly greatly improved the average B vitamin intake of the whole population. Supplements of multiple synthetic vitamin preparations have not been found to improve the physique or health of school children as a whole (Bransby *et al British Medical Journal* 1946 1 193).

One can only conclude (a) that more tests are needed on children of this age group before any confident answer can be given and (b) that in the meantime a healthy scepticism is not unreasonable. Nevertheless (c) some kind of wheat germ preparation forms a nutritious and palatable, if somewhat expensive, addition to the diet, and the writer's own inclination would be to use it occasionally in any normal child's diet and to try pushing it for underweight children.

#### Persistence of Ankylostoma Infestation

**Q**—*Can ankylostomes breed in the gut? How long can they persist after a patient has left an endemic area? Some months ago I recovered a large number of ankylostomes from the bowel of a patient who returned to this country from Assam five years ago and to day I saw an ex-officer who returned from Siam three years ago with a moderately heavy infestation. As neither of these patients could have been reinfested since their return I shall be interested to have your views on the subject.*

**A**—The persistence of infection in the patients referred to is in accordance with the belief that adult ankylostomes may live for as long as six years. Ankylostomes cannot multiply in the gut, the larvae hatched from eggs passed in the faeces becoming infective only after further development during a free-living existence. Cases of reinfestation in persons returning from abroad have not been recorded in this country but it has recently been shown that, if the blankets and night clothes of patients with hookworm disease are stored under damp conditions, workers in a laundry may become infected by handling such fomites. It is therefore possible, although very unlikely, that under exceptional circumstances reinfestation might occur in this country.

#### Sulphonamide Excretion in Maternal Milk

**Q**—*If a nursing mother develops a streptococcal tonsillitis and is put on full doses of sulphonamides how much if any is excreted in the milk? If so is it excreted in its original form and in a concentration great enough to harm the baby?*

**A**—Sulphonamides are excreted in maternal milk but the concentration attained is considerably less than that in the blood. Suppose the latter to be 10 mg per 100 ml—an adequate therapeutic concentration—and that the infant gets 30 oz (about 835 ml) of milk daily, the amount of the drug consumed daily by the infant would be under 0.05 g. Since at least twenty times this amount can be administered to infants therapeutically, it will be understood that this small dose is unlikely to have any harmful effect.

#### "Parpanit" and "Diparcol"

**Q**—*Could you please give any information on parpanit and diparcol with special reference to their use in Parkinson's disease?*

**A**—The treatment of Parkinsonism with 'parpanit' which is a diethylaminoethyl ester of phenylcyclopentane carbonic acid was described by Dunham and Edwards in the *Lancet* of Nov. 6 1948 (p. 724). They find that its action is similar to that of hyoscine or of tincture of stramonium. The side effects of parpanit differ somewhat from those of hyoscine, some patients are likely to tolerate the former better than the latter and vice versa. Diparcol is the diethylaminoethyl derivative of thiodiphenylamine which has been introduced in France for the treatment of Parkinsonism; its use is still being investigated.

#### Benedikt's Syndrome

**Q**—*What is Benedikt's syndrome?*

**A**—Various syndromes have been described in connexion with lesions of the crus cerebri. A lesion of the peduncle is recognized by a homolateral lesion of the third nerve with a contralateral hemiplegia most pronounced in the face (Weber's syndrome). The oculomotor palsy is often incomplete. When the lesion extends caudally and involves the red nucleus it may produce tremor and ataxia on the contralateral side with a homolateral oculomotor lesion. This latter condition is known as Benedikt's syndrome.

#### Wedge Shoes for Genu Valgum

**Q**—*What type of wedge shoe would be suitable for a child with incipient knock-knee?*

**A**—Almost every case of early genu valgum deformity will respond to efficient and long continued wedging of the shoes. It should be emphasized, however, that the wedging must be maintained continuously throughout a prolonged period often of years. The wedge should be at the inner side and should measure 3/16 in (0.47 cm) in thickness at its base. It is usually affixed to both sole and heel, but it is probable that heel wedges alone are equally effective. The most convenient method is to have the wedges applied by an expert shoe repairer, who will usually insert them between the layers of the leather rather than affix them direct to the surface.

#### Testosterone and Testicular Atrophy

**Q**—*It is said that testosterone, even in small doses produces testicular atrophy. Should this preclude its use in cases of diminishing sexual function in the early middle aged?*

**A**—Testosterone does tend, in large doses to produce some testicular involution. This is not true of small doses, and in any case it is not a contraindication where there is clinical evidence of the need for replacement of an organic deficiency by testosterone. A diminished sexual function in middle age is to some extent physiological and protective. It may, however, be psychological, or associated with the intensity of the daily problems of modern life. Testosterone should not be given unless the physician believes that he is dealing with a deficiency of testosterone secretion unassociated with the above factors.

#### NOTES AND COMMENTS

**Aid to China**—The chairman of the Sheffield Committee (British United Aid to China) writes to say that his committee has two objectives: (1) to support a chair in one of the British linked medical schools of China, and (2) to supply Sheffield made goods needed in hospitals, universities, and schools sponsored by British interests. The China Christian Universities Association will administer the funds financing the chair. The need of the Chinese people is desperate, particularly for hospital instruments. Donations will be gratefully accepted by the chairman of the Sheffield Committee, 15, Endcliffe Hall Avenue, Sheffield, 10.

**The Thirty Seven Club**—The club wishes to raise £250,000 to provide essential social amenities for the coloured community in Southern Rhodesia. The club is appealing for a million shillings from overseas sympathizers and would gratefully acknowledge donations of a shilling or more. Postal orders and cheques should be made payable to the Honorary Treasurer, Million Shilling Fund, The Thirty Seven Club, P.O. Box 397, Bulawayo, S. Rhodesia.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Atiology*, *Westcent*, *London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1 on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Britmedads*, *Westcent*, *London*. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra*, *Westcent*, *London*.

B.M.A. SCOTTISH OFFICE: 7 Drumshoosh Gardens, Edinburgh.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 18 1948

## THE SECRETARY REPORTS

### REMUNERATION AND SPENS

The detailed account of the Spens remuneration among practitioners in a sample area, now completed, was before the Remuneration Subcommittee of the General Medical Services Committee at its meeting on Wednesday, Dec 8. Further investigations are being begun immediately in other sample areas, including rural areas. In the meantime as a matter of urgency, a deputation is to lay before the Ministry forthwith a case for an immediate increase in the Mileage Fund to meet the urgent problems in rural areas, coupled with a request for immediate payment from the Inducement Fund for practitioners who have suffered hardship in all kinds of area and who are needed in their areas. This step should not lead practitioners who have suffered hardship to defer making application to the local executive council for payments from the Inducement Fund. Naturally, some practitioners are reluctant to take this step. Nevertheless, they are urged to do so in order that an accurate measure of the loss of income being suffered should be available.

To use the Inducement Fund now does not necessarily mean that this is the ideal method for the future. On the contrary to meet the problem of rural practitioners, it is evident that the Mileage Fund is the proper source of moneys necessary to raise the average payment per patient in rural areas to a level which will ensure a proper income for those practising in the country. The Mileage Fund must be regarded as a separate fund, standing on its own feet and adequate to meet the real needs of the situation. Increases in the Mileage Fund must come from new moneys and not from the general remuneration pool.

#### The Amending Bill

The time has come to remind ourselves and the Minister of the changes that the profession expects in the amending Bill or in new regulations. Certain changes have been promised.

(1) A clause in the Bill to prevent a Minister from introducing a whole time salaried medical service by regulation, this provision also to preclude the imposition by regulation of any universal full time consultant service.

(2) The clarification of partnership problems in the light of the report of the Legal Committee on this subject. The recommendations of the Legal Committee include the naming of a new appointed day applicable to those in partnership on July 5, 1948 and the establishment of a supplementary compensation fund to meet the financial obligations under partnership agreements of those in the Service but in partnership with practitioners not in the Service.

(3) Augmentation of the global compensation fund of £66 million because the number of practitioners entering the Service is substantially in excess of 17,900. It is believed to be approximately 19,400.

(4) Provision to empower local executive councils to elect their own chairman and to cover the costs of local medical committees by statutory levy.

(5) Provision to enable the professional member of the Tribunal to be drawn from a panel of suitable persons.

In addition to the modifications promised others will be sought, apart from improvements in remuneration which may be dealt with under regulations made on the authority of the present Acts. Included in the changes which are likely to be sought are the following:

(a) Private patients should be enabled to obtain drugs and appliances at the public expense even though they are obtaining their medical care privately.

(b) Patients desiring to obtain their specialist treatment in private beds should enjoy, as a grant-in aid towards the cost of such provision, an amount corresponding to the cost which would have been incurred by the State had they entered public

accommodation. Further, the amount "designed to cover the cost" of private accommodation should be nationally or regionally determined at a reasonable level and the tendency to exorbitant charges should be reversed.

(c) The Act should be amended so as to make unnecessary the detailed schedules of fees chargeable to patients treated in private wards.

(d) Medical staff committees should be statutorily recognized and have the right to be represented on boards of governors and hospital management committees. In the case of teaching hospitals the right to representation on boards of governors is conceded though the medical committee is not recognized in the Act. In the case of non teaching hospitals the present position is that the hospital management committee must include some members appointed by the regional board after consultation with the senior medical and dental staff employed at the hospital or hospitals of the group. This is regarded as unsatisfactory. The position should be that the medical staff or staffs of the hospital or hospitals under the hospital management committee should establish their own medical committee, which should be statutorily recognized, and that this medical committee should be the body to appoint to hospital management committees. Further, the medical advisory committee to the regional hospital board should stand in the same relationship to that body as the medical committee of a teaching hospital has stood in relation to the board of governors in the past.

(e) There should be established proper machinery to protect specialists from arbitrary or unjustified termination of their appointment by boards of governors or regional hospital boards.

(f) The block transfer of public patients should automatically follow the selection by the Medical Practices Committee to the declared vacancy, the transfer being made to the practitioner finally selected.

(g) Appeals from the decision of a local executive council on applications for basic salary should be made not to the Minister but to the Medical Practices Committee.

(h) The necessary amendment should be made to empower local executive councils to remove from their lists practitioners no longer working in the area and no longer providing the appropriate premises.

#### Consultant Co-operation

The Royal Colleges, Royal Scottish Corporations, and the Consultants and Specialists Committee of the British Medical Association, recognizing the urgent need for a body to speak for consultants with one voice, have agreed to establish a Joint Committee with the following terms of reference:

(a) to represent consultants and specialists in the impending negotiations with the Government on matters arising out of the National Health Service Acts and the report of the Spens Committee on the Remuneration of Consultants and Specialists,

(b) to prepare and to submit for the consideration of its constituent bodies a scheme, including terms of reference, for the future work of the committee.

By the time these words appear the committee will have had its first meeting, held on Friday, Dec 17.

#### Capitation Fee

The statement at the end of my report of Nov 27 should be amplified to read, 'The payment on account at the end of the year will be based on the number of patients on lists on Oct 30, 1948. The payment on March 31, 1949, will be based on the numbers on lists on Dec 31 1948.'

# National Health Service

## REPRESENTATION OF CONSULTANTS AND SPECIALISTS

### JOINT COMMITTEE ESTABLISHED

The exploratory committee set up at the conference held on July 28 of representatives of the Royal Colleges, the Royal Scottish Corporations, and the British Medical Association met at the Royal College of Surgeons on Dec 10 under the chairmanship of Sir Lionel Whitby. It was agreed that

(1) It is essential in the interests of the consultants that a joint committee of the bodies concerned should be established to speak for consultants with one voice

(2) The terms of reference of the Joint Committee should be

(a) to represent consultants and specialists in the impending negotiations with the Government on matters arising out of the National Health Service Acts and the report of the Spens Committee on the Remuneration of Consultants and Specialists,

(b) to prepare and to submit for the consideration of its constituent bodies a scheme, including terms of reference, for the future work of the committee

(3) Where a constituent body disagrees with the view of the Joint Committee on a proposal put forward to the committee the constituent body shall be entitled to have its view represented to the Government, provided that, before any such representation is made, a conference between representatives of the Joint Committee and the constituent body is held in an endeavour to reach agreement

(4) The Joint Committee should appoint joint secretaries to the committee, one nominated by the Colleges and Corporations jointly and one by the British Medical Association

(5) On the question of the composition of the joint committee it is suggested that it is desirable that in the representation of constituent bodies on the Joint Committee there should be representatives of both teaching and non teaching interests

The following composition of the committee is agreed

Royal College of Physicians	3
Royal College of Surgeons	3
Royal College of Obstetricians and Gynaecologists	2
Royal College of Physicians, Edinburgh	1
Royal College of Surgeons, Edinburgh	1
Royal Faculty of Physicians and Surgeons, Glasgow	1
Consultants and Specialists Committee established by the British Medical Association	6

## BASIC SALARY

### MORE APPEALS DECIDED

The Minister of Health has made his decision on a number of appeals by doctors against the refusal of a local executive council to grant a basic salary. We summarize below the facts of some of the cases.

A doctor practising in a small town estimated that he had suffered since the appointed day a 50% decrease in his income which was previously nearly £5,000. In appealing against the decision not to allow him a fixed annual payment he said that he would gain little or nothing financially if he received the £300 but would have established a principle.

The executive council stated that the doctor had nearly 2,300 patients on his list that this number was sufficient to provide him with an adequate income, and that the doctor would not gain financially from a fixed annual payment.

In deciding not to allow the appeal the Minister took account of the following factors: (1) The facts did not show any reasonable justification of the kind envisaged in E.C.L. 44 for allowing the appeal. (2) In view of the number of patients on the doctor's list it was doubtful whether the doctor would suffer any financial loss by the decision and it was possible that he might even gain financially.

In June 1948 a doctor over 65 years of age started a practice in a seaside town. He stated that his decision to move to that district had been partly due to reasons of health and increasing age.

The executive council, in declining to grant his application for a fixed annual payment, said that the doctor had only 29 patients on his list, that there was very little likelihood of his accepting as many as 500 patients, and that he could not be regarded as building up a practice. They considered that it was a case of a doctor taking up practice in semi retirement.

The Minister, in deciding not to allow the doctor's appeal, took the view that payment of the £300 to a doctor taking up practice again in semi retirement in an area where it was not clear that his presence was necessary for securing an adequate medical service, would not satisfy the condition that there must be reasonable justification for the payment.

Shortly before July 5 a doctor set up in practice in a village in which there had been no resident doctor. In appealing against the decision to withhold the fixed annual payment, he said that a resident doctor was needed in the village and that he was relying on the payment to meet his living expenses while he was building up the practice.

The executive council said they had been advised by the Medical Practices Committee that the council's area was 'over-doctored,' and contended that it was improbable that the number of patients on the doctor's list would reach 500 within two years.

In allowing the appeal, the Minister took account of the following factors: (1) The doctor was starting a new practice and would suffer hardship without the £300. (2) The number of doctors in the area was not relevant to the granting of the fixed annual payment. The appeal was allowed on condition that the position was reviewed in a year's time.

Two doctors, husband and wife, practising in partnership in a rural area, each have rather over 400 National Health Service patients. The executive council granted the application of the husband for a fixed annual payment but refused that of the wife on the ground that the number of patients in the area could be adequately served by one doctor.

In appealing against the decision to withhold the fixed annual payment from the wife, the two doctors stated that they were in practice on an equal partnership basis, and consequently both applied for the £300. They considered the decision to withhold the payment contrary to Para 4 of the leaflet 'Remuneration of General Practitioners.'

The executive council contended that the district could be served adequately by one doctor and, prior to the partnership, had been so served for a considerable number of years, during which the practice was subsidized under the National Health Insurance Act.

In deciding not to allow the appeal, the Minister had regard to the following factors: (1) The £300 had been approved in the case of the husband. (2) The fixed annual payment was intended to serve as an assurance during a period of uncertainty. In considering whether this condition obtained, the position of a woman doctor practising in partnership with her husband could not be considered in isolation from that of the husband.

## DENTISTS' INCOME

### ANNUAL LIMIT TO BE IMPOSED

Recent reports in the Press about the earnings of dentists under the National Health Service must have excited the admiration of doctors everywhere anxious about their own inadequate remuneration. Mr L. C. Atkins, of the Public Dental Service Association has said (*Manchester Guardian* Dec 6), 'There are ten or twelve dentists in the country who are making £12,000 a year gross and about 74 who are making, say, £6,000 gross. He goes on to say that expenses take away rather more than half of that amount. One dentist is even said (*Daily Express* Dec 7) to have gross earnings at the rate of £40,000 a year.

The Minister of Health announced on Dec 9 in a written Parliamentary reply that he intends to limit dentists' earnings as follows:

'With the dental associations I am undertaking a full review of our present translation of the Spens Committee into fees for services. Meanwhile, as it is obvious that some dentists are earning far more than that Committee ever contemplated, I am adopting a temporary arrangement whereby fees are reduced by half after a dentist reaches an income of £4,800 gross—or £1,000 in excess of

the point at which the Spens Committee said the risk of bad dentistry began. Doctors already have a limit, in the number of patients allowed on their lists."

The Council of the British Dental Association stated on Dec 11 that the Minister had taken this action without investigating the alleged incomes or the circumstances in which they were earned, and without giving the profession any opportunity of making such an investigation. It emphatically condemned the action of the Minister in limiting by regulation the earnings of dentists who are working extremely long hours in the effort to provide the service which the public has demanded. His action, in the opinion of the association, is an attack on the liberty of the individual and is against public interest as leading to the inevitable curtailment of an essential health service. The association has refused an invitation by the Minister to appoint representatives to watch the operation of the amending regulation and to advise on any necessary modification. It will await a clearer definition of the functions and duties of these observers.

It may be recalled that the Spens Report on the remuneration of general dental practitioners suggested that 33 chair side hours a week (equivalent to 42 working hours a week) 'represent full but not excessive employment and that generally speaking, employment in excess of these hours tends to impair efficiency'. The Report recommended, however that additional remuneration could be earned by practitioners able to work more than 1,500 chair side hours a year without loss of efficiency. Basing his argument on the Spens Report the Ministry of Health official (*Manchester Guardian loc cit*) said that 'it was provisionally agreed that the gross income should be £3,800 subject to review, but the Ministry is taking the figure £4,800 because there is a shortage of dentists and some overtime is inevitable'.

The main Spens recommendation on the remuneration of general dental practitioners in a publicly organized service was as follows:

If there were sufficient dental practitioners in relation to the demand for their services to secure a spread of incomes comparable to that in 1938, arrangements should be made to ensure that between 35 and 54 years of age 75% of those practitioners should receive net annual incomes of over £850, 50% of them should receive incomes of over £1,100, and 25% incomes of over £1,400. By net income we mean gross remuneration less the professional expenses allowed for purposes of income tax. These recommendations are expressed in terms of the 1939 value of money.

Dentists seem to have obtained a more favourable interpretation of their Spens recommendations than general practitioners have done. Apart from that, however, doctors may well feel alarmed at the conduct of a Minister who suddenly proposes to reduce remuneration that has already been agreed on. The effect of his proposal would simply be to reduce the number of hours worked by dentists and thereby deprive some patients of speedy treatment.

## AUSTRALIAN HEALTH SERVICE

The Australian National Health Bill has now passed both Houses. Speaking in the debate on the Bill, the Prime Minister Mr Chifley, is reported (*Manchester Guardian* Dec 10) to have said, 'I have a suspicion that the people who represent the British Medical Association in Australia are shell-backed old Conservatives. If the B.M.A. continues its present attitude to the National Health Bill the Government will train its own young doctors by sending them abroad for study and specialist training. It would be a disgrace to humanity if the B.M.A. refused to co-operate with the Government'.

## THE WELSH COMMITTEE

The Welsh Committee at its last meeting considered proposals for its reorganization so that it should be fully representative of the profession in Wales and able to canalize the views of the Branches and Divisions where concerted action and mutual discussion are needed. The views of all the Divisions in Wales are at present being sought and will be considered at a special meeting of the committee when it is likely that a proposal will be formulated for submission to the Council.

## INDUSTRIAL INJURIES ACT

### MEDICAL APPEAL TRIBUNALS

The Minister of National Insurance has set up medical tribunals under the National Insurance (Industrial Injuries) Act, 1946, to deal with appeals from decisions of medical boards on the assessment of disablement resulting from industrial accidents and disease.

The tribunals will meet when necessary in a number of towns throughout the country, and notice of the meetings will be published locally. Each tribunal consists of a chairman, who is a lawyer, and two medical members drawn from a panel of consultants. The chairmen have been appointed by the Minister of National Insurance on the recommendation of the Lord Chancellor or the Lord Advocate, and the medical members on the recommendation of the heads of universities with medical faculties (in London, the Presidents of the Royal Colleges of Physicians and Surgeons).

The following table shows the chairmen and places of meeting.

Region	Chairman of Tribunal	Place of Meeting
Northern	Mr L J Tweedy	Newcastle - upon Tyne
East and West Ridings	Mr C Raymond Hinchcliffe K.C.	Leeds
North Midland	Sir Arthur Probyn Jones Bt	Nottingham
Eastern	Sir Thomas Creed K.C.	Cambridge
London	Sir Charles Law J.P.	London
Southern	Sir Ronald Pollock	Oxford
South western	Sir Alfred Wort	Bristol
Wales	Mr Hilda C. Jones K.C.	Cardiff
Midland	Mr His	Birmingham
North western	His	Manchester and Liverpool
Scotland	Mr C J D Shaw Mr T P McDonald K.C.	Edinburgh Glasgow

## WORKMEN'S COMPENSATION

### DAMAGES AT COMMON LAW

The Council of the Law Society has issued the following statement to the Press Association:

"Prior to July 5, 1948 a workman frequently consulted a member of the legal profession as to his rights under the Workmen's Compensation Acts, and in very many cases he was told to his own surprise that he might successfully make a claim at Common Law against his employers for damages."

'The Council's attention has recently been directed to the fact that a workman who is unaware of his Common Law rights will now, in all probability, automatically make his claim to State insurance and will never receive the benefit of legal advice. In view of the pending abolition of the doctrine of common employment by the Law Reform (Personal Injuries) Bill, it may be that in the near future there will be a greatly increased number of workmen who could if properly advised successfully make a claim at Common Law, and the Council accordingly feels that steps should be taken to bring to the personal notice of all workmen that their rights are not confined only to the receipt of State insurance.

'In reply to a question in the House of Commons on Sept 21 last, Mr Griffiths, the Minister of National Insurance, stated that he could not undertake to advise people as to their Common Law rights. The Council has accordingly asked me to draw your attention to the position and to express the hope that you will feel able to give publicity to the fact that a workman may be entitled in addition to his claim to State insurance, to damages at Common Law."

## GIFT TO CORPUS CHRISTI COLLEGE

The Masters and Fellows of Corpus Christi College, Cambridge, have expressed their grateful thanks for the gift which members of the B.M.A. who resided in College for the Conference in June gave for the purchase of a piece of plate. They have bought the following pieces. Two wine coasters by Paul Storr (1814), and one silver mustard pot by Charles Fox (1804). The following inscription is being engraved:

DONO DEDERUNT E SOCIETATE BRITANNICA MEDICINAE  
PLERIQUE DOCTISSIMI MENS IVN AD MCMLXVIII

The following has been added to the coasters: *ἡαῖρ ἡαῖρ - ἡαῖρ* ('Rejoice and drink')

## Questions Answered

We publish here the answers to a selection of questions that seem to be of general interest

### Obstetric Fees

**Q**—A patient was brought to me for her confinement. I gave the usual antenatal attendance and examinations and was called to attend her in labour. But an obstetric emergency developed and I had to arrange for her immediate admission to hospital. Am I entitled to the 7 guineas fee?

**A**—Yes, if your name is on the local obstetric list. If it is not a fee of 5 guineas is payable.

### Ophthalmic Certificates

**Q**—When a school-child requires only replacement or repair of glasses must I complete Form OSC 2?

**A**—Where replacement or repair of glasses only is required, Form OSC 10 should be completed. But if, as a routine, sight-testing is included, Form OSC 2 should be completed at the same time.

### Secretarial Assistance

**Q**—My out-patients clinics are so long that by the time they are finished the secretarial staff of the hospital has left and I have to do my letters at home with the help of my own secretary and at my own expense. Can I obtain an allowance for this?

**A**—There is no provision for secretarial assistance other than that supplied at the hospital concerned. One result of this is that many consultants are finding their clinical work is limited because of the heavy burden of correspondence.

### Unnecessary Visits

**Q**—One of my patients asked me to visit him knowing full well that the visit was quite unnecessary. He offered me a fee for that admittedly unnecessary visit. Am I permitted to take it?

**A**—No. The only circumstances in which a fee may be accepted by a practitioner from a patient on his National Health Service list (or on the list of his partner or assistant) are

(a) When a person claims to be on a doctor's list and fails to produce a medical card, the doctor having given any necessary treatment may demand and accept a reasonable fee provided he either renders an account or gives a receipt. If within 14 days the patient applies to the local executive council for a refund of the fee and the council finds that he was on the doctor's list, the council may recover the fee from the doctor repaying it to the patient. (A person seeking treatment as a temporary resident is not required to produce a medical card.)

(b) From any statutory body in respect of service rendered for the purpose of that body's statutory functions—e.g., fees for notification of infectious diseases.

(c) From any school, employer, or body for the medical examination of persons for whose welfare the school, employer, or body is responsible—e.g., appointment as a part-time works medical officer.

(d) For treatment outside the range of service given in private hospital accommodation or nursing home provided the practitioner is on the staff of a hospital providing hospital and specialist services under the Act, and provided that the practitioner returns the appropriate form to the local executive council within seven days after the date of rendering the treatment.

(e) Under Section 16 of the Road Traffic Act, 1934.

### Charging for Certain Certificates

**Q**—When dealing with N.H.S. patients for whom certificates are required under the Lunacy, Mental Treatment or Mental Deficiency Acts must all certificates be given free of charge?

**A**—No. The only certificates for which charges may not be made are as follows:

(a) To certify under Section 55 (8) of the Lunacy Act, 1890 that detention of a person absent on trial is no longer necessary.

(b) To certify under Section 335 of the Lunacy Act, 1890, that a person is incapable of managing his own affairs.

All other certificates including 'recommendations' under the Mental Treatment Act can be charged for. The Association recommends that the fee should be not less than two guineas.

### No Payment for Telephoning

**Q**—In order to obtain admission to hospital for certain patients I have to make trunk telephone calls. This is expensive. Is there any payment for this?

**A**—No, not at present. This matter was discussed by the General Medical Services Committee and representations will be made. The committee is recommending to the Ministry that all calls other than local should be reversed.

### Refund of Superannuation Contributions

**Q**—In the case of Superannuation after Less Than Ten Years' Service (Questions Answered Supplement Nov 27 p. 194), would not the retiring practitioner be entitled to receive in addition to his own contribution of 6% the Ministry's contribution of 8%?

**A**—If no benefit is payable, the retiring practitioner's contributions are refunded with compound interest at 2½%. The Ministry's contributions are not refunded.

## HEARD AT HEADQUARTERS

### Visitors From Abroad

Counsel's opinion has been taken on whether overseas visitors are covered by the National Health Service Act, and it looks as if they are although the words of the Act are not free from ambiguity. As has been said 'An overseas visitor can come here and get a denture, an artificial leg, a corset, a pair of spectacles, and a wig, all for nothing, saving as much as his trip has cost him.' This seems to be part of the Act which has not been well thought out.

### For the Pocket

The *Annual Handbook* for 1948-9 is again a very useful compilation, a miracle of compression, sitting neatly in the pocket and yet containing everything that the B.M.A. man wants to know. A special section is devoted to the organization of the Association face to face with the National Health Service—the composition and function of the two new big committees, each of them nearly as big as the Council itself—the General Medical Services Committee under the chairmanship of Dr. Wand, and the Central Consultants and Specialists Committee under the chairmanship of Mr. Newell. Then we have the Local Medical Committees and the Regional Consultants' Committees, the specialist groups in the Association, and the Public Health Committee concerned with the public health service. Another new feature is an outline of the Empire Medical Advisory Bureau and its committee under the chairmanship of the Past President, Sir Hugh Lett. We are also given the names and addresses of clerks of executive councils and of senior administrative officers and secretaries of regional hospital boards.

### Abbreviations

The medical students are following in the wake of their seniors in their liberal use of abbreviations—those initials which assume in the reader a store of information on the subject. The following passage occurs in a message from the president of the British Medical Students Association. At the A.G.M. we discussed the relationship which should exist between the B.M.S.A. and the M.F.B. of I.U.S. The conclusions of the S.I.C.C. were used as a basis for discussion. This kind of conciseness now becoming so popular in medical discussions may sometimes be confusing. Thus 'P.M.' may stand for post mortem or prostatic massage. 'A.P.' for an antero-posterior ray view or for artificial pneumothorax, and one is left sometimes in doubt whether 'M.O.H.' refers to a medical officer of health or to his superiors in Whitehall.

### The Chronic Sick

The interest shown in the aged and chronic sick—an interest which the B.M.A. through its special committee can claim to have done much to awaken—was demonstrated at Friends House, London, during a recent week-end, when gatherings of

nearly a thousand people from all parts of the country discussed the welfare of old persons. The difficulty of the hospital problem was put frankly by Dr Trevor Howell, physician in charge of the geriatric unit at St John's Hospital, Battersea. He mentioned a surgical ward in one well-known hospital where eight old ladies, all of them suffering from a chronic condition, had been for an average of two years. On the assumption that the average stay of an acute case in a surgical ward is three weeks, these old ladies have taken up the accommodation of about 280 acute surgical cases. Dr Howell repeated the remark of one old man when told that no hospital bed could be found for him, "They have hospitals for children, why can't they have hospitals for old people like me?" Why not a Great Ormond Street for the aged?

## Local Administration

### Tuberculosis Regulations

It is now necessary to gain information about men born in the year 1931 likely to be called up for military service who have a history of tuberculosis states the Ministry of Health (Circular 175/48). The Minister therefore requires the appropriate medical officers of health to send forthwith the necessary particulars in respect of all male registered persons born in that year, and to comply in other respects with the Public Health (Tuberculosis) Regulations, 1940, as now applied to this age group. The information should be given on form T 147. The changes affecting the tuberculosis services brought about by the NHS Act do not modify the procedure.

### Distribution of Basic Salary

The basic salary is being paid to some doctors whose names are on the lists of more than one executive council. The Ministry of Health states (E.C.L. 112) that the council paying it to the doctor should recover the appropriate proportion from the other councils concerned, so that the moneys available from the central pool may be distributed equitably. The appropriate proportion for each area is that which the number of patients on the list of the doctor in that area bears to the total number of his patients. This adjustment should be made for the September and December quarters.

## Correspondence

### Car Expenses of Whole-time Specialists

*The following letter has been sent to the secretary of the Central Consultants and Specialists Committee with the request also that it be published in the British Medical Journal*

SIR—We the undersigned whole-time specialists in Leicester are seriously concerned over the Circular H.M.C. (46)48 of August, 1948 issued by the Ministry of Health, which sets out the conditions under which allowances for car expenses are to be paid and the method of calculation of the amount thereof, and understanding that negotiations are proceeding between your committee and the Ministry beg to submit the following considerations in the hope that they may be of use to your committee, or at any rate informative to it as to what is the attitude of certain whole-time specialists.

It is felt by us that a scale which may be appropriate for a general body of persons who normally work at a fixed office or headquarters and who know in advance what their daily travelling commitments will be, is completely inadequate for such as ourselves.

As you know we are officially attached in most cases to one hospital but may be and in fact are in many cases called upon to visit other institutions during the course of our duties, and for this individual transport is absolutely essential. As has been said it is not known beforehand in most instances when these journeys may have to be made and hence the means of transport must be available instantly if required. The individual cannot,

therefore, as the majority of those to whom the circular refers, decide to take his car from his residence to his main place of work on one day but not on another.

In addition to this, whenever we may be at home or out on private or social visits, etc., we are liable to receive a summons to attend at a hospital as quickly as possible in the case of emergencies or to undertake a domiciliary visit. Obviously a car must be available for this purpose, as the emergencies may occur any time during the day or night. In a nutshell we would be quite incapable of carrying out the work inherent in our appointments without the use of a car.

To have a car available in such circumstances as those briefly indicated certain fixed commitments are involved—viz., wear and tear or depreciation of the car itself, tax, and insurance. It is obvious that repairs, petrol, etc., naturally vary with the mileage run. To pay only a fixed allowance of 6d per mile for journeys from the recognized headquarters and possibly although this is not mentioned in the circular, for emergency visits to headquarters outside ordinary working hours makes an insignificant contribution to such fixed charges, as in the majority such journeys are, although of great urgency, relatively infrequent.

We feel, therefore, that as it is absolutely essential for us to have a car in order to enable us to perform our duties the costs of such provision should be covered by the payments made. This implies a scale which would recognize

(1) That the car must be taken every day from the place of residence to the headquarters so that it shall be available for the specialist concerned instantly in time of need.

(2) That, even though the mileage covered may be and frequently is small, the overhead or irreducible expenses must be wholly incurred in addition to the varying running costs dependent upon distance covered.

Although no doubt all or many of the above points will have been already considered by the committee, we feel it would be well that you should be acquainted with our feelings in this matter and trust that your negotiations on behalf of us all will be fruitful in the arrival at an equitable agreement.—We are, etc.

### The Betterment Factor

SIR—It appears from Dr M. Hutchinson's letter (*Supplement* Nov 13, p. 177) that Mr Bevan is satisfied that the recommendations of the Spens Committee on the remuneration of general practitioners are being implemented. We hope that vigorous steps are being taken by our representatives to disabuse his mind of any idea he may have that the G.P.s share his satisfaction. Apparently there may be some difficulty in convincing him that 17s 5d post-war is not the same thing as 15s 6d pre-war. We hope that the following two statements made earlier this month by official sources will assist in throwing light on the so-called betterment factor by which the pre-war 15s 6d will have to be adjusted.

Figures published in the *Monthly Digest of Statistics* for October show that, over a wide range of industries examined, operatives' earnings had increased by an average of 114%, between October, 1938 and April, 1948—with incidentally a reduction in working hours. Also, we note that Mr Dalton speaking in the Commons on Nov 2, said "The wholesale prices index showed an increase of 118% over pre-war" (*Daily Telegraph* Nov 3).

It appears, therefore, that the proposed capitation fee of 17s odd is about one-half of what is due to us according to the Spens Report, and this takes no account of the increase of work since July 5.

We would like to know why we are expected to continue working the NHS on half-pay, and when may we expect a full adjustment, retrospective to July 5, to be made? The Minister, as a good trade unionist, should be brought to see the bare justice, having regard to all the circumstances of a

capitation fee of 35s per person per annum. Should he fail, however, in spite of all our efforts to be persuaded, is not the proven remedy in our own hands?

Though the above is the principal defect requiring urgent rectification there are others such as the unenviable position of rural and semi-rural doctors, the three months wait for cheques, and so on which have already received some publicity in your columns. We have seen no reference, however, to the injustice of a system of payment which rewards experience in one section of the profession but totally ignores it in another. We ask that before long serious consideration will be given to devising a revised method of remuneration for GPs—one which will recognize the fairly obvious fact that the services of a doctor of 20 years' experience are on the average more valuable to the community than those of a recently qualified entrant. We are, etc.,

BIRMINGHAM BERNARD E WALL H P DALY

### Payment for Temporary Residents

SIR—Doctors in holiday and health resorts normally get a considerable part of their income from summer visitors and convalescents, the former, at any rate, usually paid cash down in the old days. Since July 5 we have been accepting these patients as temporary residents and so far have received no payment at all and I have not yet been able to discover when, how, or on what scale payment is eventually to be made. Our local executive council has still no information, and I have searched the pages of the *Journal* in vain for any reference to the subject, although my fellow practitioners are becoming increasingly impatient and outspoken at the non appearance of their earnings for the summer season.

There is also some anxiety about the method of payment for these patients. If the money is to come from the general pool and involve a further whittling down of the capitation fee, we shall consider ourselves unfairly treated as compared with doctors in industrial towns, for their patients come to us in the summer and not vice versa. At least it is to be hoped that we shall not be told that we are being "subsidized by our fellow practitioners" and required to submit to a means test before we are paid for our services—I am, etc.,

Westgate-on Sea

G M ADDISON

SIR—I am informed by the clerk to the East Sussex Executive Council that up to Dec 1 'no instructions have been received from the Ministry of Health in regard to the method of payment in respect of temporary residents'. I wish to protest against the way in which the Minister of Health keeps us waiting for the niggardly sums which are due to us—I am, etc.

Hove Sussex

W F DE C VEALE

\*.\* The Secretary of the Association writes: Payment for temporary residents is one of several payments to doctors which are governed by the distribution scheme for the area. Executive councils are still waiting for a model distribution scheme which the Ministry is preparing. The Ministry has been asked to deal with the matter as one of extreme urgency.

### Remuneration of MOs H

SIR—I am anxious to hear what is the position with regard to the negotiations for the new salary scales for all medical officers in the employment of local health authorities, and whether Whitley Council machinery for these negotiations has been set up. I know that this matter has now been under consideration for over a year and it seems to me that our profession is the only one under the National Health Service which is not taking advantage of this machinery.

At present the question of remuneration of medical officers in the Public Health Service requires to be settled as a matter of urgency. It is neither possible to obtain suitable replacements at the present salaries paid by local authorities nor in some cases to retain the present staff. Unless the Association takes prompt steps to solve this matter along the proper lines I can foresee a distinct falling off in membership and the encouragement of 'break-away' associations. I should like

to state that the local authority medical officers in Scotland are strongly in favour of the adoption of the Whitley Council machinery for negotiation and are most dissatisfied with the present unsettled position—I am, etc.,

Glasgow

STUART LAIDLAW

\*.\* The Secretary of the Association writes: The Association is pressing for negotiations to be opened. The present position is summarized in the *Supplement* of Dec 11 (p 214) under the heading 'The Secretary Reports'.

### Rural Practitioners

SIR—May I point out through the medium of your columns the peculiar difficulties some doctors in rural districts have to face and which to my mind entitle them to a generous allowance from the Inducement Fund without further ado.

Although my practice is a rural one in a hilly district, it is unique in having two or three coal mines where most of the men find employment. The high incidence of chest complaints associated with that calling adds considerably to the attention they require through the winter months. This, coupled with the visiting and innumerable minor accidents, more than doubles the work in comparison with my counterpart in the town. Another factor arising from the extreme hilliness of the locality is the unusual position of a large number of the cottages. Each one is perched at the top of a rough steep path, or buried in an equally deep gully. Climbing to and from these places is a stiff and breathless affair, and after constant daily repetition it is not surprising that cardiac and cardiovascular disorders become very prevalent with the onset of the early fifties.

Dealing with such conditions is part of my daily work, and I feel that others in like circumstances should not be overlooked when practices are classified according to the difficulties that have to be overcome in giving reasonable attention to all classes of the community. Furthermore, I would state that cars in such areas do not have a satisfactory life of much more than two years. Every three months the tyres on my car require retreading and so do my boots. However I hope to carry on until my arteries need relining, when I shall be obliged to give up, in the hope that by then a portion of the Marshall Aid will be allocated for the relief of old and worn out doctors—I am, etc.

Blakeney Glos

J M ASHTON

SIR—I have been waiting for the report of the Conference of Local Medical Committees (*Supplement* Dec 4 p 203) for a clear statement of the aim for putting rural practitioners on a reasonable basis of remuneration. To oversimplify I think that it should be recognized that there is a maximum number of patients (say 2000) which a rural practitioner can attend, and I feel that he should be enabled to receive the same net income as a town practitioner with 4000 patients. Apparently this can be done in three different ways:

- (1) A different capitation fee for rural patients, which I think is quite undesirable.
- (2) Inducement payments to all rural practitioners, which I think is again undesirable.
- (3) A very big increase in the mileage allowance.

Should this principle be established it would mean that the rural practitioner's average mileage allowance per patient should at least equal the capitation fee at whatever level it is finally adjusted. If the average rural patient lives four miles from his doctor, the mileage allowance would then be 4s 6d per patient mile per annum—I am, etc.

Kirkby Lonsdale Westmorland

JOHN W CROWTHER

### Salaries of Opticians and GPs

SIR—I feel that Mr G H Giles's letter (*Supplement* Nov 27, p 196) on the payment of opticians calls for some comment. May I with all respect suggest that six hours is not a full day's work, representing as it does just half the working day of the average general practitioner? Surely Mr Giles must realize that a man doing half a day's work cannot expect more than half a day's pay?

The question of time occupied by dispensing is not very relevant. After all it is paid for. Even if the whole work is done by a firm of manufacturing opticians the "ophthalmic optician" still gets his retailer's profit. If he does any work

on the glasses himself he receives the corresponding payment. In any case, even if one concedes Mr Giles's figures and allows a five day week and two weeks holiday a year, the optician will have an income from refractions alone of £1,125.

Mr Giles complains that he is only paid for dispensing when the glasses are delivered to the patient. This is surely the usual time to pay for things and he would not appreciate it if all who sold him goods insisted on cash several months in advance.

Among his expenses Mr Giles mentions "secretarial assistance." Surely it must be considered wasteful for a man seeing only six patients a day (Mr Giles's claim) to employ a secretary? Perhaps without undue fatigue he could work 6½ hours a day and write his own letters. The items given for rent, rates, lighting, and insurance will be the same for a G.P. and so need not be considered further. The 101 unspecified items I find a little difficult to enumerate. I can think of heating, cleaning, postage, stationery, subscriptions, and books—all of which will be required also, some to a much greater extent, by the G.P.

Now let us look at the G.P.'s expenses which the optician is under no obligation whatever to incur. He has to keep a car, which must be in serviceable condition continuously, he must be on the telephone, there must be someone to answer the telephone and door, day and night, 365 days a year, he must bear the majority of the cost of drugs and dressings actually used by him.

One expects to receive payment appropriate to one's ability, and it is reasonable to assume that on the whole our profession is of greater ability than the opticians (although in business acumen our negotiators appear to have much to learn). One expects to receive payment on account of a long and expensive training, and there can be no doubt that the doctor's training is much longer and more expensive than the optician's. One expects to receive extra payment for night work and overtime—two things that never disturb the placid waters of the optician's easy life. In industry it is usual to pay danger money to those exposed to any risk, yet we are coughed over by the tuberculous and diphtheritic, who would be far too ill to go near the optician, moreover, a glance at the obituary columns in the *JAMA* will convince any medical practitioner of his enormous liability to coronary disease.

It is usual moreover to receive something for the time spent "on call" though not actually working, Mr Giles should remember that whereas he can do what he likes after he shuts his shop at 5 p.m., the G.P. is still not free when he has finished his evening surgery at 8 p.m.

I must agree with Dr M. J. Ingram (*Supplement* Oct 30, p 153). Opticians (like dentists) are at the moment being grossly overpaid, whereas the sum paid to G.P.s is niggardly in the extreme—I am etc.

Silver End Essex

J. W. NICHOLAS

SIR—Mr G. H. Giles, secretary to the Association of Optical Practitioners, refers (*Supplement* Nov 27 p 196) to an estimate based on a working week of five days and offered in an entirely different context some time ago before figures could be available. He states that it is not possible for an optician who undertakes dispensing in addition to testing sight to serve twelve clients in a six-hour day but that the average number seen by an optician is nearer half that number per day.

Quoting from actual figures, over 5,500 completed forms were received in one month from 26 opticians and nearly 5,200 in the succeeding month from 26½ opticians (a new applicant was included in the latter half of the month). On a basis of 24 week-days in each month (allowing for the half day closing customary under the Shops Act) the figure gives an overall average per optician per day in one instance of almost exactly 9 and the other of 8.2. These figures might seem at first sight to support Mr Giles's contention, were it not that they are averages of the work of all opticians, of which some reserve a very considerable part of their time for other optical work than that under the Supplementary Ophthalmic Service, some are but recently established, since release from the Forces, and a few engage actively in other business (e.g., pharmacy). Mr Giles does less than justice to the endurance of one optician who averages 16 completed forms per day over a period of three consecutive months.

Neither the quickest nor the slowest worker is necessarily the most accurate or most conscientious. An optician however, can devote more than six hours in any one day to Supplementary Ophthalmic Service work if he wishes, with corresponding augmentation of his income on a payment per-case basis. On the other hand, a weary doctor can only increase the quality of and remuneration for each item of service by curtailing those services.

Unduly dilatory payment for services rendered and undisputed is highly unsatisfactory. Doctors are dissatisfied with the payments they are receiving on account at the end of each quarter, but an

optician receives each month in settlement for sight-testing fees a cheque which, on the figures quoted, will amount on average to about £150, and should amply meet establishment expenses. The cost of finished spectacles will not be debited to him by the manufacturers until after delivery, and as this is effected he may expect to receive prompt reimbursement of their cost. In addition, he will draw "on average" £250 per month or more in respect of the associated dispensing fees, accumulated as a sort of non-interest bearing Government security or nationalized savings, from which the less actively employed may apply for payment on account as needs demand.

The distinction has been drawn between this sum of £400 and upwards per month, which the "average" optician may increase by his own exertions, and the £400 per quarter paid to the "average" general practitioner, subject to increase only if in future there should be fewer doctors to share a fixed pool—I am, etc.

Hull

D. STENHOUSE STEWART

### Mileage Fund

SIR—We rural practitioners are having and are going to have a thin time, but our position is not going to be made any easier or more comfortable by the information in "The Secretary Reports General Practice" (*Supplement* Nov 27 p 191), in which we are told, "Mileage payment will on average be slightly more than double." We all know that we have "on average slightly more than double" the number of patients on risk that we had before July 5. If this is so, I consider it a misrepresentation of the facts destined to give us a false impression. If misrepresentation is too strong a word it is surely, at best, a withholding of very relevant facts—I am, etc.,

Wokingham Berks

RALPH ROSE

\*\* The Secretary of the Association writes. The words quoted have no bearing on the question of the adequacy or inadequacy of the mileage fund, to which reference is made elsewhere. They mean no more than that the pre-Act mileage fund amounted to £600,000 and the Act mileage fund is £1,300,000.

### Polish Medical Association

SIR—As the result of recent legislation many Polish doctors now in this country are obtaining permanent registration, which should entitle them to every form of medical practice recognized by the Ministry of Health. But registration is only the first essential step towards finding a job, as everyone knows. There are others to be taken, some of which may be pretty hard even for the best of us. It is in order to facilitate this process that we wish to let it be known that our organization which has enjoyed the friendly relations of the British Medical Association right from the beginning, is willing to assist anyone in finding suitable partners, assistants, hospital officers, etc., by supplying necessary information and arranging interviews.

Our office is at 48, Wilton Crescent, S.W. 1, and the telephone number is SLOane 1735, office hours being Monday–Friday 6–8 p.m.—We are etc.

A. FIUMEL

Chairman

K. DLUZNIEWSKI

Honorary Secretary

### Demand for Certificates

SIR—Your article "NHS" (*Journal*, Nov 13, p 864) prompts me to submit the following points for your consideration.

(1) The present NHS is a compromise between a full-time salaried service and a capitation system, with the evils of both.

(2) Once we have been compelled to accept the elimination of private practice (this is what the NHS amounts to), we should have accepted the full-time salaried service. This would have saved us from the present picture of hundreds of practitioners faced with serious economic difficulties.

(3) The NHS has not appeared yet in full bloom, it will mature when the thousands become eligible for sick pay and will come pestering the doctors for certificates ("I have paid for it") which the doctor (who unfortunately has to eat three, time a day) dare not refuse.

(4) A full-time salaried service would have allowed us (a) to organize hours of duty with relief for the womenfolk, (b) some relief from the degrading position, in which we find ourselves at

...of yes men for any request from our clientele whether reasonable or unreasonable (c) to be in the position of refusing to issue a certificate without worrying at the same time, 'This will mean so many units withdrawn'—I am, etc,

Manchester

B HIRSH

### Maternity Medical Service

SIR—The Minister's circular 173/48, reprinted in the *Supplement* dated Nov 20 (p 181), has possibly regularized the position of the midwives in the new Service, but it has surely confused the issue as far as the obstetrical general practitioner is concerned. While it is true that Note 4 on the inside cover of the book containing Forms EC 24 allows for the attendance of the doctor at the confinement when he or the midwife considers this necessary, it states specifically that he shall be 'responsible for the medical supervision of the mother and child during the puerperium'. This surely must imply that he visits the home during the puerperium—indeed, Part III of Form EC 24 asks for the actual dates of these visits. Unless the doctor has been sent for to deal with an emergency during labour he must depend upon the midwife to inform him when the baby is born, and if he is to be responsible for the mother and child during the puerperium she (the midwife) must be prepared to take instructions from him.

In the main this is probably a hypothetical difficulty, as midwives in general will undoubtedly welcome the new interest which doctors will be able to take during the puerperium. However, I have a specific case in mind where the midwife refuses to inform me when she has conducted a normal labour even when the case has been booked on Form EC 24. In addition, she insists that all advice during the normal puerperium should be given to the mother by her. The local supervising authority is unable to solve the difficulty. The obvious solution is that the doctor should fulfil all the conditions of Rule E 20 of the Central Midwives Board and regard the nurse as a maternity nurse in every case accepted for maternity medical services. Few of us would be prepared to inflict this indignity on all midwives, and even if it were possible to deliver all cases personally midwifery as a branch of nursing would in consequence disappear. Yet how is the obstetrical G.P. to be certain that he is going to be able to honour his legal obligation to the mother who has booked him for maternity medical services?

If the Minister is of the opinion that the supervision of the mother and child by the doctor during the puerperium is unnecessary, then the wording of Note 4 attached to Form EC 24 should make provision for the doctor attending during the puerperium 'only if required to do so by the midwife in attendance'. I feel reluctant to complete any further Parts I of Forms EC 24 until this point is cleared up—I am, etc,

Brenchley Kent

W B HOWELL

### Relation with Executive Councils

SIR—I have followed with great interest the correspondence started by Dr Hugh M. Tucker and Dr D. Gwynn Jones (*Supplement*, Oct 9, p 134) and continued by Dr Robert Forbes (*Supplement* Oct. 23, p 147, and Nov 27, p 195) and Dr J. Arthur Gorsky (*Supplement* Nov 13, p 176). Dr Forbes is surely right in his contention that we are not 'servants,' and he is certainly right when he says we must continue to be members of a recognized protection society.

I would refer my learned friend Dr Gorsky to Pollock, *Torts* p 64—adopted by McCardie, J., in *Performing Right Society v Mitchell etc Ltd* (1924 K.B. 762 767-8). An independent Contractor who undertakes to produce a given result, but so that in the actual execution of the work he is not under the order or control of the person for whom he does it and may use his own discretion in things not specified beforehand.

I would respectfully submit that the first schedule of SI 1948 No 506 does not indicate that we are anything other than independent contractors in our relationships with our respective executive councils. The above-mentioned SI refers to terms of service and includes a general description of the rights and duties of patients and practitioners. There is however, no instruction as to how the work is to be executed and obviously the practitioner is left to use his own discretion in all matters

not specified beforehand. But it could be argued that under

Range of Service S 6 (2), practitioners who contract to perform maternity services are ordered when to examine their patients, and I would agree that this is an unfortunate clause.

To quote from the *Medical World* (April 9 p 5) 'These are precise indications of the treatment required such as we never thought to see incorporated in regulations. But we feel that general practitioners will not be much concerned for the reason that few G.P.s will be disposed to undertake those services.' Personally I have not applied to do midwifery, and in any event the obstetrical contract is a separate one.

In conclusion I would agree with Dr Gorsky and Dr Forbes that the issue is a most important one and for the sake of Dr Tucker and others I hope that it will be clarified by a more able and learned pen than mine—I am, etc,

Leicester

JOHN A CHAPEL

### Basic Salary

SIR—Before the inauguration of the National Health Service opinion as expressed in your columns undoubtedly conveyed the impression that the majority of the profession was against the granting of a universal basic salary. The Negotiating Committee, in no uncertain terms, made this known to the Minister of Health, who, having seen the red light in this particular instance climbed down, and the idea of the universal basic salary was abandoned in favour of that of an optional one, which was again apparently discarded to give place to the unsatisfactory means test system which is at present causing so much discontent.

The profession, as far as I know, has been given no opportunity to approve this latest and exceedingly important development, and it is quite obvious that a considerable body of opinion is against the method employed now in granting basic salaries. It would even appear that a steadily increasing number of general practitioners are beginning to see the inherent good sense and equity of Mr Bevan's original proposal. An unsavoury situation is developing in which one section of the profession accuses the other of living on the charity of its fellows while the accused complain bitterly of being misled with regard to the basic salary and of having to suffer the humiliation and indignity of undergoing a means test in order to obtain it.

It is quite ridiculous to blame the Minister in the present crisis. The responsibility for this situation rests entirely on the shoulders of the Negotiating Committee, and there seem to be grounds for doubting that in this instance the committee has furthered the true desires of the profession. Under the circumstances it seems obvious that steps should be taken in a true democratic way to find out what those in general practice really do think in this matter. With its past experience the Association should have no difficulty in organizing a ballot for this purpose. I suggest that all general practitioners be asked to vote for or against a universal basic salary. I do so because I am convinced that if there is to be a basic salary, and at the same time peace and good will among practitioners, that basic salary must be paid to all.

No matter what the result of such a ballot might be it would of course be necessary to continue payment of those salaries already granted. One would gather that they are few in number and would only be required for a few years—I am, etc,

Glasgow

JOHN A FRASER

### Graded Remuneration

SIR—I strongly support the opinions of Dr F. W. Cheese (*Supplement* Sept 11, p 199, and Nov 27, p 196). With the modern demand for medical attention, no general practitioner can exercise reasonable skill and due care if he undertakes the responsibility of more than 2 000 or 2 500 patients. A list of over this number makes for hurried slipshod work, wholesale reference to hospital, and a complete lack of interest in medicine—that is, it makes for general practice at its worst.

If as a profession we are to maintain and indeed improve our standards and do justice to our patients, then something must be done to restrict lists, and to this end I recommend doubling the present capitation fee for the first 2 000 or 2 500 and thereafter payment at the rate of one tenth per caput.

Should it be argued that on this basis there are insufficient doctors to attend the population, then I submit there are many

young men and ex-Service practitioners who find themselves unable to get a look in whilst the established practitioners and those who sat tight during the war have lists of four, five, or even six thousand. This contention is supported by the large numbers of applications received by executive councils when vacancies are advertised. Furthermore, there are, in round figures, 20 000 practitioners and 45 million population. Let us live let live, endeavour to make the best of this very bad job, and above all let us do good work—I am etc.,

Wolverhampton

J C B BONE

### Professional Expenses and Size of Lists

SIR,—Two matters in the *Supplement* of Dec 4 are desirous of comment in order to clear up regrettable ignorance.

In the report of the Conference of Local Medical Committees (p 203) Dr A W Weston is reported as saying that he "did not know any practice where 35% expenses would be allowed by the Inland Revenue." It is a sad commentary on the profession's representation when such is allowed to go unchallenged. For the last accounting year my expenses as agreed with the Inland Revenue were 53% of my gross. As mine is an entirely rural practice in which the gross is obviously likely to drop considerably this year, the expenses are I think going to be at least 60%, taking into account the extra mileage, drugs, and telephone calls in the NHS.

Secondly, in the "Points from Letters" (p 212), although in agreement with most of what he writes, "Dare Quam Accipere" states the rural practitioner "cannot make a living out of 2,500 or so patients, and his idleness is not due to choice." Well, Sir, for some seven years before taking over this rural practice I had a large practice in industrial Lancashire with some 2,400 NHI patients, so probably in all some 6,000 patients. I can assure your correspondent that 2,500 patients in a truly rural practice take as much time to deal with efficiently as double that number in an urban area. To back that assurance let me give him a few figures well known to all rural practitioners.

I am allowed petrol for 500 miles a week. One mile with another if an average of 30 miles an hour is sustained, this means 16 hours actual driving each week, the equivalent of  $1\frac{1}{2}$  working days. In my 23 villages I attend five surgeries daily except Sunday. I dispense for the whole of my practice, which in the first three months of the NHS entailed 1,981 items, each to be dispensed, corked, labelled, noted, and wrapped, names and addresses written, and 1,320 sent out by car to be delivered at the appropriate one of ten depots from which the patient collects. Each time a patient goes to hospital for consultation or emergency, a first sixpenny phone call to make the appointment and then a second one to arrange transport.

These are only outstanding instances of how an 80-hour week is made up servicing some 2 600 patients, but there is one point in which "Dare Quam Accipere" is greatly at fault: in my case the idleness is of choice—I am, etc.,

TRULY RURAL G P

### POINTS FROM LETTERS

#### False Position

D H V DEAN (London, NW 3) writes. The indecently rushed second plebiscite, for which I have never yet had a trustworthy explanation, dumbfounded the profession, and the lack of clarity in the circular on the Council's own views completed the confusion. In the words of another, "The B.M.A. was stampeded into taking up a false position, with its consequent loss of prestige and authority." It is easy to stand aside and say, "They asked for it, let them stew in their own mess." It is more laudable to try by every means, including the support of a proposed new organization, to prevent the mess getting worse.

#### Press for Full Settlement

D I N SAMUEL (London, SW 11) writes. The scheme has now been extant for some four months, ample time in my opinion for gross irregularities to be straightened out. I should like to give a few examples. (1) Owing to the dilatory methods and a lack of realization of the urgency of the matter, an interim payment only has been made for the following alleged reasons: (a) the number of basic salaries to be paid has not yet been determined, (b) inflation of fees and it would appear that we stand no hope of receiving full capitation fee until after March 31. How many of us thought there would be queries about the basic salary? I myself have heard more than one member of the Council proclaim (prior to July 5) that it

was just a matter of arithmetic—according to the numbers on the list—as to whether basic salary was claimed or not: no hint of a means test was ever given. (2) No payment has been made for obstetric services, nor is any acknowledgment made of forms rendered. (3) No mileage fee in full has yet been paid to our country colleagues, but perhaps their cars can be run free of cost during deliberations. I feel that a sense of urgency and realism among the powers that be in our Association could have combated such a situation. Let the Divisions call meetings of their constituents and hear their stories and let them press for full settlement by Jan 1 1949.

### Remuneration of G P s

Dr G T A HASTINGS (Birmingham) writes. The capitation method of payment is, at the present rate, quite inadequate to maintain our former income. Compensation is to be paid for loss of the right to sell the goodwill of practices, but no suggestion has been made for compensation for "loss of annual income" say, over a twenty- or thirty-year period. It would be a fair deal if the Minister made up doctors' incomes to their former level. As he is not likely to do so the remedy must lie with the doctors themselves. The usual workers' [sic] remedy, the strike, is beneath professional dignity and tradition, mass resignations would torpedo the scheme, but we ourselves would go down with it, as the public can no longer afford private treatment. Negotiations are usually long-drawn-out, an immediate short-term policy must be pressed for between the Negotiating Committee and the Ministry. The purpose of this letter is to invite comments and suggestions from fellow practitioners along the line of immediate increase of capitation fee with limitation of lists, or payment on a basis of actual services rendered, as in some countries abroad. Immediate action is necessary. Let the Negotiating Committee do its job expeditiously or make way for better men.

## Association Notices

### NATHANIEL BISHOP HARMAN PRIZE

The Council of the British Medical Association is prepared to consider the award of the Nathaniel Bishop Harman Prize in the year 1949. The value of the prize is approximately £100. The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has been previously published in the medical press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1949 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

The writer of the prize winning essay may be required to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association. Each essay must be typewritten or printed in the English language, and must be distinguished by a title and a motto. The essay must not bear the name of the writer, which should be sent with the essay in a sealed envelope bearing only the motto on the outside.

Essays must be forwarded to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W C 1, not later than March 31, 1949. The title of the proposed essay and the motto should also be notified in writing to the Secretary by Dec 1, 1948, and should not be accompanied by the writer's name. The prize will be awarded at the Annual Meeting of the Association to be held in 1949. Inquiries relative to the prize should be addressed to the Secretary.

### SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for research scholarships as follows. An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These

scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given other things being equal to members of the medical profession.

Each scholarship is tenable for one year starting on Oct 1, 1949. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the award of the Insole Scholarship of the value of £250 for research into the causes and cure of venereal disease.

Applications for scholarships must be made not later than March 31, 1949 on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

### PRIZES FOR MEDICAL STUDENTS

The Council of the British Medical Association is prepared to consider the award in 1949 of prizes to medical students for essays submitted in open competition. The subject of the essays for 1949 shall be "The Value of Observation in the Training of the Medical Student." The purpose of these prizes is the promotion of systematic observation among medical students. In awarding the prizes due regard will be given to evidence of personal observation. No study or essay that has previously been published in the medical press, or elsewhere will be considered eligible for a prize.

The following prizes are offered:

**National Prizes**—six, each of the value of £25

**Regional Prizes**—as detailed below, based on the four Regions of the British Medical Students Association

London Region, 6 prizes (1 of the value of £15 5 of the value of £7)

Midland Region, 3 prizes (1 of the value of £15, 2 of the value of £7)

Northern Region, 3 prizes (1 of the value of £15 2 of the value of £7)

Scottish Region 5 prizes (1 of the value of £15 4 of the value of £7)

Any medical student who is a registered member of a medical school in Great Britain or Northern Ireland at the time of submission of the essay is eligible to compete for the prizes. The winners of the National Prize will be ineligible for the award of a Regional Prize. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final. Should the Council of the Association decide that no essay entered is of sufficient merit, no awards shall be made.

Each essay must be typewritten or written legibly in the English language and must be unsigned and accompanied by a detachable sheet giving the name of the candidate, his medical school, and his B.M.S.A. Region. Essays must be forwarded so as to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1 not later than March 31 1949.

### PRIZES FOR NURSES

The Council of the British Medical Association is prepared to consider the award in 1949 of three prizes each of the value of 20 guineas for the best essay and three prizes each of the value of 10 guineas for the second best essay submitted in open competition by each of the following categories of nurses: (i) Pupils nurses, (ii) State registered nurses working in a hospital, (iii) State registered nurses not working in a hospital—i.e., district nurses, private nurses, etc.

The subjects of the essays for 1949 shall be: category (i) "What discipline do you think necessary in the training of nurses?" category (ii) "What part of nursing duties can be delegated to others with safety?" category (iii), "The care of old people in their own homes."

The purpose of these prizes is the promotion of systematic observation among nurses. In awarding the prizes due regard will be given to evidence of personal observation. No essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Nurses who are undergoing training at a hospital are eligible to compete under category (i); nurses registered by the General Nursing Council are eligible to compete under categories (ii) and (iii). If any question arises in reference to the

eligibility of a candidate or the admissibility of his or her essay the decision of the Council of the British Medical Association shall be final. Should the Council decide that no essay entered is of sufficient merit no award shall be made. Each essay must be typewritten or legibly written, must be unsigned and must have attached to it a sealed envelope containing the name and address of the candidate and the category into which he or she falls. Essays must reach the Secretary of the British Medical Association not later than March 31, 1949. Inquiries about the prize should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

### Meetings of Branches and Divisions

#### ASSAM AND N. BENGAL BRANCH

At the Annual General Meeting of the Branch held at Jinn under the chairmanship of Dr C. G. Terrell on March 7, Dr B. Chatterjee, Medical Officer, Chargola Valley Medical Association, read a description of a case of bristly dysentery complicated by malaria and ankylostomiasis. He described how a woman labourer attended complaining of a long standing colicky pain in her abdomen and of passing frequent watery motions day and night. She looked fairly well nourished but somewhat anaemic. On examination nothing much wrong was found in her except some tenderness over her liver which was not enlarged. On examination of her stools a very large number of actively motile *Balantidium coli* were found in the sample and also many trichomonas. Some undigested starch and fat were detected. She was admitted to hospital.

When admitted she had high fever. Benign tertiary malaria parasites were found in her blood. She was put on mepracrine tablets 1 d.s. for five days. Her fever left her the next day. Her stools were examined after seven days when numerous vegetative *Bal coli* were still found, and many Charcot-Leyden crystals. At this time she developed more tenderness over her liver. In view of this and the presence of Charcot-Leyden crystals in the stools although no *Entamoeba histolytica* were found a course of emetine hydrochloride by injection and kurchi and bismuth mixture by mouth was given her. This treatment relieved the tenderness on her liver but in her stools there were still plenty of *Bal coli* so we concluded that anti amoebic treatment was no cure for *Bal coli* infestation. Then we put her on to chiniofon 10 gr (0.65 g) t.d.s., and also lavage for two weeks and after that lavage with dimol for a further week as we ran short of chiniofon. But after this course of treatment she was still discharging vegetative *Bal coli* and trichomonas and some ascariis ova were detected. At this time for the first time fully formed balantidium cysts were seen some at the stage of cyst formation and binary fission, and several of them were found in intimate pairs. Perhaps if we could have persisted with this treatment long enough a cure might have been brought about but unfortunately we ran short of chiniofon and dimol.

At this time ankylostoma ova were found in her stools and she was put on carbon tetrachloride and oleum chenopodii but this treatment did not eradicate the *Bal coli* though hookworm disappeared. She had another attack of malarial fever and was given another course of mepracrine.

By this time her general health was greatly improved, her diarrhoea stopped and her colicky pains had disappeared. She was symptomatically cured, though not microscopically.

I got her readmitted to hospital on Feb 5 and started to give her hydrarg. bismide 2 ml of 3% solution on alternate days. After the first injection the number of *Bal coli* fell from innumerable to only under 12 under a 7/8 in. cover slip and their movement was sluggish. But in the next week after three injections the number increased to 27 and in the week after another three injections to 23. Movement of the parasites remained somewhat more sluggish than before. At last on March 4 after 11 injections her stool became free of *Bal coli* for the first time. These remained free after repeated daily examination though innumerable trichomonas were still present. I have kept her under observation to see if the offending parasites reappeared once again in her stools. The patient is cured to all purposes she does not suffer from any symptoms, her colic and diarrhoea have ceased to bother her any longer and her general health is much improved. This was the third case of *Bal coli* infection that I have seen and treated during my thirty years of practice.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are under stood to require employees to be members of a trade union or other organization.

**Metropolitan Borough Councils**—Fulham, Hackney, Poplar.

**Non-County Borough Councils**—Dartford, Radcliffe (limited to future appointments), Wallend.

**Urban District Councils**—Denton, Droylsden, Houghton-le-Spring, Hutton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

## THE NERVOUS AND HUMORAL CONTROL OF GASTRIC SECRETION\*

BY

GEORG KAHLSON, M.D., K.M.

*Professor of Physiology University of Lund Sweden*

It is a well-established fact that food substances, or the products of their digestion, when in contact with the pyloric mucous membrane cause a secretion of gastric juice. The mechanism by which the gastric glands are stimulated to secrete during the chemical phase is still a subject of controversy. The importance of the pyloric region as a receptive surface for chemical substances is shown in experiments by Sawitsch and Zelony (1913), of the Pavlov school, on dogs with an isolated pyloric pouch and either a gastric fistula or a Pavlov pouch. The introduction of chemical substances such as meat extracts, peptone, and acetic acid into an isolated pyloric pouch produced a secretion of juice from the glands of the fundus and corpus.

The Russian investigators further demonstrated that mechanical stimulation of the pyloric region also causes the cells to secrete acid and pepsin. If, however, the body of the stomach and the pyloric region are separated surgically and chemical substances are then introduced into the main stomach through a fistula no gastric juice is secreted either by the pouch or by the stomach. One of the theories advanced to explain this phenomenon involves the liberation from the pyloric region of a special hormone, "gastric secretin," as suggested by Edkins in 1906, later referred to as "gastrin." Edkins's idea was based on the observation that extracts from the pyloric mucosa when injected into a vein stimulate the gastric glands to secrete, while similar extracts from the fundus and body of the stomach have no such effect. Edkins regarded the action of gastrin on the gastric glands as analogous to that of secretin on the pancreas.

Among more recent workers Gregory and Ivy (1941) confirmed the operation of a hormonal mechanism in initiating gastric secretion, although they consider that the pyloric region is not essential in eliciting secretion of a transplanted fundic pouch on perfusion of the main stomach with secretagogues. In later experiments, however, Grossman, Robertson and Ivy (1948) found that distension of the pyloric portion of the stomach stimulates the secretion of hydrochloric acid by the fundic glands. This finding is regarded by these authors as conclusive evidence for the existence of a pyloric hormone for gastric secretion.

### Vagus Stimulation

In our laboratory, under the leadership of Uvnas, the problem of gastrin was approached from a quite different angle. Stimulating the vagi to the stomach under proper

conditions initiates secretion of gastric juice, which proceeds at a fairly high rate so long as stimulation of the secretory nerves is continued. In such experiments Uvnas (1942) observed that if the blood supply to the pyloric region was obstructed the response of the gastric glands to vagal stimulation was reduced or nearly abolished. This observation indicated that the pyloric region might be instrumental not only in the chemical phase but also in the nervous phase of gastric secretion. The part played by the pyloric region in the nervous phase of gastric secretion was examined in experiments of varying types, as follows (Uvnas, 1942).

In anaesthetized cats the main blood supply to the pyloric region can easily be obstructed by ligating the pyloric branches of the hepatic artery. After ligation of the arterial supply to the pyloric region the secretion of watery acid juice during vagal stimulation decreases considerably and abruptly, from 37 to 8 ml in a typical experiment, the juice also changes in character and becomes highly mucous and poor in hydrochloric acid.

I have already referred to experiments by Sawitsch and Zelony, who obtained secretion from the gastric glands by introducing chemical substances into an isolated pyloric pouch. These workers also observed that after cocaineization of the pyloric mucosa there is no secretion in the main stomach on chemical stimulation of the pyloric region. In a typical experiment of this type on cats (Uvnas, 1942) the vagi were stimulated for sixty minutes, which yielded about 16 ml of acid watery juice. The stimulation was discontinued and the pyloric mucosa was rubbed with a 2% solution of cocaine hydrochloride. After a resting period of forty-five minutes the vagi were again stimulated during three and a half hours of maximal vagal stimulation only a few drops of mucus were secreted, not until approximately six hours after cocaineization did the rate of secretion return to normal. Cocaine does not inhibit the secretory mechanism by paralysing the acid- and pepsin-secreting cells, because histamine injected slowly into a vein or given intramuscularly evoked secretion in cats after cocaineization of the pyloric mucosa. Cocaine given intramuscularly in doses sufficient to paralyse the respiratory centres did not significantly diminish the secretory response to vagus stimulation if the pyloric region was left functionally intact.

### Resection of Pyloric Region

In another series of experiments Uvnas resected the pyloric region in cats and dogs. The resection included the distal part of the stomach from that closely proximal to

\*A 5<sup>th</sup> civil lecture (abridged) given at the University of London on May 21 1948

the *meisura angularis* to that just distal to the pylorus. In cats secretion decreases considerably after resection of the pyloric region. In dogs the effect of pyloric resection is still more striking. In one dog abundant secretion persisted during two hours of vagal stimulation. After resection of the pyloric region gastric secretion during vagal stimulation decreased to a negligible amount and the gastric juice completely changed character: the juice contained no free hydrochloric acid and was of a stringy mucous consistency.

All these experiments indicate that on stimulation of the secretory nerves to the stomach some active agent, or agents, is liberated in the pyloric region, and from here this agent is carried to the parietal cells. More direct evidence of a hormonal mechanism within the nervous phase of gastric secretion was obtained in cross circulation experiments on cats (Uvnas, 1942). The pyloric mucosa of the

they identified chemically as histamine sulphate or picrate. These experiments were presented by Ivy and his co-workers as strong evidence that histamine may be a gastric secretory hormone liberated from the pyloric region and that histamine and gastrin are identical. I will come back to histamine, but will first turn to the work on gastrin carried out in Babkin's laboratory and in ours.

Komarov (1938a, b), in Montreal, approached the problem from a new angle, and so did Uvnas and his group in Lund. Whereas their predecessors, like Ivy and his group, had extracted the non-protein substances from the pyloric mucosa, eliminating the protein fraction so far as possible, the Canadian and Swedish workers searched for gastrin under the assumption that it might chemically be related to secretin, which, as shown by Hammarsten and Ågren in Stockholm, is a protein-like body. Komarov in 1942, using several methods of extraction, obtained preparations from the pyloric mucosa which on intravenous injection stimulated gastric secretion both in anaesthetized and in unanaesthetized animals. Komarov's preparation contained no histamine.

In our laboratory Uvnas (1943, 1944, 1948) and his group obtained a preparation of gastrin having a degree of purity which compares favourably with the best commercial preparations of secretin. The active principle is a protein-like water soluble substance iso-electrically precipitated at a pH of about 4 to 5.5. Chemically, gastrin shows great similarities to secretin. Both substances are contained in the sodium chloride and the trichloroacetic acid precipitates. They are alike in their solubility in some organic solvents and in their degree of stability in

acid and alkaline solutions. But they differ in some other respects—e.g., in their solubility in ethyl alcohol.

#### Activity of Gastrin Preparations

The activity of gastrin preparations is assayed in our laboratory on cats anaesthetized with a mixture of chloralose and urethane. Comparisons are made on the following standard: the activity of the extracts is measured as the quantity of gastric juice secreted in the hour following the beginning of the injection, which is made in the iliac vein at a rate of 0.4 ml per minute for thirty minutes. One secretory unit of gastrin is the quantity which produces a secretion of 1 ml of acid juice per hour in a cat weighing 2–3 kg. (Gastrin, like secretin, is effective only when injected direct into the blood stream; intramuscular injections induce a very scanty secretion.) Purified preparations of gastrin do not contain histamine in detectable amounts.

On intravenous injection of gastrin, secretion usually begins in about five minutes, gradually increases for five to ten minutes, and then proceeds at a more or less constant rate. When injection is interrupted, secretion continues for ten to fifteen minutes at maximal rate, then gradually declines and reaches the basic level approximately thirty minutes after the end of injection.

Table I (Uvnas, Munch-Petersen, and Ronnow, 1944) illustrates the activity of the preparations during the different stages of purification. Crude preparations from the pyloric mucosa of pigs obtained by precipitation with hydrochloric acid extracts with 20% sodium chloride contain one secretory unit in 45 mg, whereas with the pure

Cats under chloralose. Pyloric region of the recipient functionally eliminated by cocaine. Cross circulation experiment demonstrating the liberation of a hormone (gastrin) from the donor cat's pyloric region on stimulation of the vagi.

recipient was functionally eliminated by cocaine. The carotid artery of this cat was then anastomosed with the donor cat's coeliac artery, and the donor's superior mesenteric vein with the recipient's jugular vein. The portal vein and the hepatic artery of the donor cat were ligated. Since the superior mesenteric vein was ligated distally to the inflow of the gastro-splenic vein, the venous outflow from the donor's stomach and pyloric region was diverted to the recipient's jugular vein. Clotting was prevented by heparin. On stimulation of the recipient cat's vagi for forty-five minutes (see Chart) only a scanty flow of Congo-negative juice was secreted. If, however, the donor cat's vagi were also stimulated the stomach of the recipient started to secrete and free acid appeared in the juice. When stimulation of the donor's vagi was interrupted, gastric secretion ceased in the recipient cat even if its vagi were stimulated without interruption. Identical results were obtained in cross-circulation experiments where the pyloric region of the recipient cat was resected instead of being cocaineized.

#### Production of Gastrin

These experiments suggest that, in cats, impulses from the brain, mediated by the vagi, cause the liberation in the pyloric mucosa of some agent which, carried by the blood stream, stimulates gastric glands to secrete acid juice. What is the nature of this secretory excitant and what physiological properties can be ascribed to this agent, which for the sake of simplicity we can refer to as gastrin? Ivy and his group (Sacks, Ivy, Burgess, and Vandolah, 1932) made a fresh attack on the gastrin problem in 1932. Using 80% acidified alcohol as a solvent they extracted from the pyloric mucosa of a hog an active agent which

TABLE I—Gastric and Pancreatic Secretion after Intravenous Administration of Crude Alcohol Washed or Purified Substances from the Pyloric Mucosa of Cats and Pigs

Active Material Type of Purification	Cat	Gastric Secretion	Pancreatic Secretion
A A crude trichloroacetic acid precipitate from cat	75	12 ml	11 drops
The trichloroacetic acid precipitate from the above washed with 80% ethyl alcohol	65	10 ml	0
B A preparation from pig precipitated with 20% NaCl and 10% trichloroacetic acid	50	9 ml	5 drops
A preparation from pig precipitated with 20% NaCl and washed with 80% ethyl alcohol	40	7.5 ml	0
A preparation from pig purified by the trichloroacetic acid method	40	14 ml	0
Secretin	5	0	41 drops

preparations one secretory unit is contained in 2.3 and 2 mg respectively. Comparison with the activity of a commercial preparation of secretin, pincrotest, considered to be of a high degree of purity, showed that at least 3 to 5 mg. of this preparation must be introduced into a vein of a cat to produce a definite pancreatic secretion.

The gastric juice secreted on injection of purified preparations of gastrin was always strongly acid, the total acidity usually exceeding 150 milliequivalents per litre. The peptic power of the juice declined to a very low level during the course of the secretion, indicating that gastrin activates only the parietal cells.

Crude preparations of gastrin were sometimes contaminated by secretin or some other agent which stimulated pancreatic secretion. The pancreatic excitant can be removed by washing with 80% ethyl alcohol.

As judged by present experimental evidence gastrin selectively stimulates the parietal cells. Salivary, pancreatic, peptic, or bile secretion, gastric motility, blood sugar and blood pressure are not influenced by intravenous injection of doses which evoke a copious secretion of gastric juice. These observations indicate a specificity of gastrin as pronounced as that of secretin, which selectively activates pancreatic glands, causing the secretion of a sodium bicarbonate solution of low enzyme content.

In cats, dogs, and pigs the active agent, here referred to as gastrin, is predominantly present in the pyloric mucosa. The confinement of the stimulating agent to the pyloric region in these animals, together with experimental evidence that the humoral mechanism of gastric secretion is chiefly related to this region, indicates that the active agent of pyloric extracts is identical with the gastric hormone, the existence of which was postulated by Edkins forty years ago.

When we discussed these problems with colleagues experienced in human gastric surgery we encountered useful criticism. We have been told that, in patients in whom the pyloric region has been removed in cases of peptic ulcer, acid gastric secretion is at a very low ebb for a couple of weeks or possibly months after the resection but that secretion then gradually returns to approximately normal. Komarov (1942) reports that a gastric secretory agent can be extracted from the duodenal mucosa of pigs. It was of course of special interest to study also in man the distribution of gastrin in the stomach and duodenum. For these experiments resected portions of stomachs from operated patients were transferred to the laboratory without delay. Post-mortem material was obtained within ten to thirty-six hours of death. The gastric mucosa was divided into three parts—the pyloric, the boundary, and the corpus regions. Table II (Uvnäs, 1945) gives the rate of secretion observed in cats on injecting extracts from the three different mucosal regions of human stomachs. So far only a small amount of surgical material has been

TABLE II—Rate of Excretion Observed in Cats on Injecting Extracts from Three Mucosal Regions of Human Stomachs

No.	Case	Age	Sex	Mucosal Region						Total
				Pyloric Zone		Boundary Mucosa		Corpus		
				Volume (ml)	Secretion (mEq)	Volume (ml)	Secretion (mEq)	Volume (ml)	Secretion (mEq)	
M1	Doberman ulcer	31	M	12	6.5	11	21.5	11	14	34

M20		52	M	12	0	0	0	—	—	12

Total = the sum of the three mucosal regions.

examined, but it definitely shows that the human gastric mucosa contains a gastric secretory agent. The observations are too few to permit definite conclusions about the distribution of the secretory principle but they suggest that in man also the agent is chiefly if not entirely localized in the pyloric mucosa.

In man gastrin could also be extracted from the duodenal mucosa (Uvnäs, 1945). Of fifteen duodenal preparations from human cadavers six preparations were active where nine were inactive. However, when we consider that gastrin is rapidly destroyed by trypsin it is surprising that the agent could be detected in such a large proportion of the examined material. The presence of gastrin in the duodenal mucosa of man might be a hint that the so-called intestinal phase of gastric secretion, in line with the nervous and chemical phases is controlled by a hormone related to or identical with gastrin. Harper (1946) has reported that gastrin can be extracted from the mucosa of the hog's pyloric region and also from the upper part of the small intestine.

#### A. Pepsin-stimulating Agent

As I have already mentioned, purified gastrin does not stimulate the secretion of pepsin. If the pepsin present in the resting glands is washed out by a prolonged injection of histamine, which in itself does not stimulate peptic secretion, it can easily be demonstrated that gastrin given intravenously does not increase the peptic activity of the gastric juice, whereas subsequent vagal stimulation greatly increases the output of pepsin.

Switsch and Zelsony claimed that mechanical stimulation of the mucosa of an isolated pyloric pouch causes an increased secretion of pepsin in the main stomach. Pavlov showed that in dogs the peptic activity of the gastric juices varies with the composition of the food. All these facts suggest the existence of a humoral mechanism instrumental in the control of peptic secretion. Crude pyloric preparations, precipitated from acid mucosal extracts by trichloroacetic acid, contain an agent which on intravenous injection augments the output of pepsin (Uvnäs, 1948). These experiments are incomplete, but they indicate the presence in the pyloric mucosa of an agent which stimulates the peptic cells.

Harper and Raper (1943), of Manchester, report that they have extracted from the duodenal mucosa a principle of protein nature which selectively activates the enzyme-producing pancreatic cells. This principle called "pincrozymin" by them, they consider to be an ally of secretin.

in the humoral control of pancreatic secretion. Further experiments will elucidate to what extent the pepsin-cell stimulating agent from the pyloric region is complementary to gastrin in the humoral control of gastric secretion.

### Histamine

Where does histamine come into this picture? What functions, if any, can be ascribed to histamine in the control of gastric secretion? I have already mentioned that Ivy and his co-workers extracted histamine from the pyloric mucosa and identified it chemically in 1932. Influenced by this result some authors were inclined to classify histamine as a hormone liberated in the pyloric region and carried by the blood stream to the glands in the main stomach. However, Gavin, McHenry, and Wilson (1933) demonstrated that the fundic mucosa contained more histamine than the pyloric, only 20% of the total histamine extracted from the mucosa of the stomach being derived from the pyloric region. Under the impression that gastrin might be identical with histamine these authors felt that their result did not support Edkins's statements.

To my knowledge no experiments have been published demonstrating or even indicating the liberation from the pyloric region of excess histamine into the blood during the nervous or chemical phases of gastric secretion. Actually, it would seem rather unwise of Nature to resort for this purpose to a substance which in concentrations in the blood plasma sufficient to stimulate gastric secretion would produce a variety of other effects, such as general vasodilatation, increase in capillary permeability, contraction of smooth muscle, and, in hypersensitive persons, even headache. Obviously the role of histamine in stimulating gastric secretion cannot be that of a hormone carried in the blood stream to all parts of the body.

Histamine no doubt possesses admirable potentialities as a physiological excitant of acid gastric secretion. However, its mode of action on the parietal cells must be other than that of a blood-carried hormone. In cats and dogs histamine is contained in large amounts in the gastric mucosa, in concentrations approximately 1,000 times higher than in the blood plasma. Histaminase, a diamine oxidase present in the intestinal mucosa, is absent in gastric mucosa, as demonstrated *in vitro* by Best and McHenry (1930). This fact should not be stressed too strongly in favour of histamine as a gastric excitant, because it was demonstrated in our laboratory that in living tissues histamine is inactivated at a very much higher rate than *in vitro*. We have obtained evidence that *in vivo* histamine is destroyed rapidly by the lymph and in the interstitial spaces (Carlsten, Kahlson, and Wicksell, *in press*).

MacIntosh (1938), using the Barsoum-Gaddum method of extraction and testing on the ileum of the guinea-pig, demonstrated in dogs that the gastric juice obtained by sham-feeding or by vagal stimulation contained a substance with the properties of histamine. We injected the gastrin obtained by Uvnäs into the blood stream of a cat and tested the gastric juice for its content of histamine. The juice contained histamine in a physiologically active form. At that time we thought that the histamine in the plasma and gastric mucosa was present in an inactive form, and that the function of gastrin might be to liberate, in the surroundings of the parietal cells, histamine in an active state and in concentrations sufficient to stimulate the acid-secreting cells (Emmelin and Kahlson, 1944). Babkin (1944) and MacIntosh (1938) have already presented a hypothesis that vagal impulses may be transmitted to the parietal cells not directly by acetylcholine but by histamine liberated locally by acetylcholine under the influence of the vagus nerves.

### Histamine Concentration of Gastric Juice

Since in our experiments the gastric juice secreted in response to injection of gastrin contained free histamine it seemed worth while to examine the histamine concentration of gastric juice secreted as a response to a variety of stimuli. From dogs with an oesophageal fistula for sham-feeding and with a gastric pouch we collected juice during the nervous and chemical phases of gastric secretion. In both phases the histamine concentration of the juice was approximately the same. Spontaneously secreted gastric juice and juice obtained on vagus stimulation, on the injection of "prisco," and on injection of acetylcholine in the lateral cerebral ventricle all contained histamine in a physiologically active form. It is striking that the histamine concentration of the juice is rather independent of the nature of the stimulus employed to activate the parietal cells. It is also striking that the histamine concentration of the gastric juice is of the same order as in blood plasma.

The parietal cells are permeable to histamine. If the histamine concentration in the plasma is raised by prolonged intravenous injection of histamine this substance appears in the juice in higher concentrations than with physiological stimuli (Emmelin and Kahlson, 1944).

I am fully aware that these experiments do not prove that histamine is actually liberated in the mucosa under the influence of gastrin or other stimuli. Emmelin and I have spent a lot of time examining the histamine concentration in the venous plasma emerging from the stomach before and during stimulation of the parietal cells. We obtained no definite evidence of excess histamine in the venous plasma from the stomach during activity of the parietal cells. This obviously does not disprove the idea that histamine is locally engaged as an excitant, since histamine may be liberated in very close proximity to the parietal cells without diffusing in detectable amounts into the blood capillaries, or the liberated histamine may be destroyed before it reaches the absorbing blood vessels. It may be appropriate here to recall that we still lack generally accepted evidence of a liberation of histamine in any type of physiological reaction. With anaphylaxis and animal poisons, so far as histamine is concerned, the situation certainly is clearer (Gaddum, 1948). Unfortunately we know of no substance which inhibits the factors responsible for the destruction of histamine in the different tissues, and we know of no substance which specifically antagonizes the effect of histamine on the parietal cells. Those engaged in this field of endeavour, however, will remain confident that Nature has not embedded the parietal cells in copious quantities of the most potent gastric excitant so far known just to seep through the secreting cells to deceive physiologists.

### Conclusion

If tentatively we try to link together the pattern of facts as they are seen so far, the contours above the horizon of unjustified speculation are as follows. Gastrin is contained in the pyloric mucosa, and in man and pigs in the duodenum as well. This agent is liberated by vagus impulses or when chemical substances such as food come into contact with the mucosal regions concerned. The liberated gastrin is carried by the blood to the fundic mucosa, where it causes some change so that histamine is liberated in quantities sufficient to stimulate the parietal cells. In this picture gastrin enters as a common factor in the nervous, gastric, and intestinal phases of acid gastric secretion.

Obviously much work remains to be done before this view can be accepted even by those who are suggesting it as a working hypothesis.

## RESULTS OF PARTIAL GASTRECTOMY FOR PEPTIC ULCER

by  
T. W. MIMPRISS, M.S., F.R.C.S.

AND

ST. J. M. C. BIRT, F.R.C.S.

(From St. Thomas's Hospital)

An attempt is here made to assess the merits of four types of anastomosis used in partial gastrectomy. The operations were performed for chronic gastric and duodenal ulcer during the six years ending Dec 31, 1946. We have excluded all cases of carcinoma, those cases of peptic ulcer in which a previous operation other than suture of a perforation had been performed, emergency gastrectomies for haemorrhage, and a few operations in which the pylorus was not removed but was excluded. The series consists of 248 patients, and in reviewing the results we have paid particular attention to (a) the immediate post-operative course, with special reference to complications due to the type of anastomosis, and (b) the functional results. These have been divided into good, fair, and poor. The result is good if the patient is satisfied with the operation and admits to no significant side effects. It is fair if the patient is satisfied with the operation but is found to have modified his diet or eating habits to avoid unpleasant symptoms. It is classified as poor when the patient is dissatisfied with the operation or when we have considered the functional result to be unsatisfactory.

The length of time since the operation ranges from one to six years, the average period being thirty-seven months. Fifteen patients have not been traced. The last known residence of eleven of these has been visited, but they had left the district and all attempts at follow-up have failed. Visits were not paid to the residences of the other four, as two were known to have left the country and two lived a long distance away.

The following four types of anastomosis were used.

Type I. An end-to-side anastomosis with an antecolic proximal loop attached to the greater curve (Fig. 1).

Type II. An end-to-side anastomosis with a long antecolic proximal loop attached to the lesser curve with a valve and a small stoma (Fig. 2).

Type III. An end-to-side anastomosis with a short post-colic proximal loop attached to the lesser curve with a small valve and a small

stoma (Fig. 3).

Type IV. An end-to-end anastomosis of the Billroth I type, joining the duodenum to the greater curvature of the stomach (Fig. 4).

### Type I. Antecolic Anastomosis

Average period since operation	61 months
Number of operations	45
Operative mortality	1 (duodenal ulcer)
Cause of death	Bronchopneumonia
Traced	
Good	18 (8 duodenal 10 gastric)
Fair	15 (4 " 11 ")
Poor	2 (1 " 1 ")
Since died	1 (1 " 0 ")
Causes of death	hemothorax (gastric) cardiac failure (duodenal) torsion of caecum (gastric)
Untraced	
	(1 duodenal 2 gastric)
Male duodenal ulcer	Very fit 4 months after operation. Changed address.
Male gastric ulcer	Good 3 months after operation. Changed address.
Female gastric ulcer	Changed address.

**Post-operative Period.**—The operation seemed to be safe and satisfactory. The only objection was that the stomach remnant was slow to begin emptying into the efferent loop. Accordingly a nasal suction tube was left *in situ* for several days until the stomach contents began to pass through into the efferent loop.

**Late Function.**—This operation is not really satisfactory. Many writers including Ogilvie (1947) have pointed out that an anastomosis of this type leads to proximal-loop filling in many cases and consequent postcibal distress. Investigations show that proximal loop reflux is present in most of the patients in this group. The barium meal can be seen to pass through the stomach remnant straight into the proximal loop; this contracts and gradually pumps its contents back through the stomach into the distal loop. In spite of the high incidence of proximal loop reflux the results are quite good some years after operation. Most patients complain of side effects for some months after the operation. Eighteen now claim to have a very good digestion. Eighteen are classed as fair; as a group these eighteen are very pleased with the operation and are living a reasonably normal life, but most of them like to rest for a period of half to one hour after their principal meal and find that certain articles of diet, especially fats and fried food, should be taken with care. The results in the following two cases are poor.

**Case 1.**—A man aged 35 at operation in 1942 had severe postcibal distress including nausea and occasional vomiting. In 1944 he was investigated at another hospital and his troubles were attributed to proximal loop reflux. Laparotomy showed no other abnormality and an entero-enterostomy was performed. The patient says that he has had little relief from this operation.

**Case 2.**—A man aged 44 at operation in 1943 has complained ever since of nausea and distension after meals. A barium meal shows considerable proximal loop reflux but no other abnormality. He has worked continuously since operation and has maintained his weight, but the functional result is a poor one.

Although most patients are well satisfied this anastomosis does not give first-class results. We suggest two reasons for this unexpected contentment with an operation which has given so high an incidence of proximal-loop reflux.

(1) All these patients were operated on at a time when only those with very large penetrating ulcers were recommended for surgery. The more severe the pre-operative symptoms the more tolerant is the patient of a moderate post-operative function.

(2) All these operations were performed at least five years ago. The symptoms attributable to proximal loop reflux become less severe with the passage of time.

We note that Watson (1947) has often used this anastomosis and has seldom detected proximal loop reflux, but it

has been a common feature in our series, and, believing it to be responsible for postcibal distress, we abandoned the method some years ago

### Type II Antecolic Anastomosis

Period since operation (Average 37 months) 1 to 4 years

Number of operations 130

Operative mortality 3

Causes of death (duodenal ulcers)  
Burst duodenal stump twisted proximal loop, pulmonary embolus

Traced 118

Good 88 (61 duodenal, 27 gastric)

Fair 19 (14 " 5 " )

Poor 6 (5 " 1 " )

Since died 5 (2 " 3 " )

Causes of death Carcinoma of uterus (gastric) pulmonary tuberculosis (gastric) carcinoma of prostate (gastric) carcinoma of lung (duodenal), not known (duodenal)

Untraced 9

(6 duodenal, 3 gastric)

Male, gastric ulcer Untraced since leaving hospital

Male duodenal ulcer Very good 2 years later

Changed address

Male duodenal ulcer Good at 6 months Changed address

Male duodenal ulcer Fair at 12 months Changed address

Male gastric ulcer Fair at 12 months Left country

Male duodenal ulcer Fit 2 months later Changed address

Male gastric ulcer Good at 3 months Changed address

Male duodenal ulcer Never reported Changed address

Male duodenal ulcer Good at 3 months Changed address

**Post-operative Period**—We have experienced disturbing complications which appear to be due to the length of the proximal loop. One patient died on the fourteenth post-operative day, and necropsy revealed a proximal loop which

was obstructed at its junction with the lesser curve and which rotated behind the stomach.

Two other patients suffered this complication—one on the tenth and the other on the fourteenth post-operative day—but were rescued by operative correction of the fault. In these two patients the symptoms were the same both suffered a severe attack of colicky pain in the left hypochondrium and both vomited gastric contents free from bile, suggesting obstruction of the proximal loop. In each case laparotomy revealed the grossly distended proximal loop

FIG 1

FIG 2

rotated behind the gastric remnant. In one an entero-anastomosis was performed, in the other the loop was untwisted and a stitch inserted to fix the proximal loop to the right of the stomach remnant.

It is impossible to say whether the primary trouble was obstruction at the lesser curve, leading to dilatation and rotation of the loop, or rotation of the loop, leading to obstruction at the anastomosis. Nor is it possible to say whether in our one fatal case, in which the duodenal stump

leaked on the second post-operative day, the leakage was due to poor closure of the duodenal stump or to pressure in an obstructed afferent loop. We have never found this complication in any anastomosis where there was no long proximal loop, and we cannot help feeling that it may add some small risk in the post-operative period. It is fair to point out that at the time these troubles occurred we were not using the stitch advocated by Maingot (1948) to anchor the proximal loop towards the right of the stomach. If this operation is performed the possibility of a loop twist should be borne in mind in the event of an attack of abdominal pain associated with a bile-free vomit.

**Late Results**—On the whole this has proved a satisfactory operation. Results in 88 cases are classified as good and 19 as fair. We have had barium meal tests of all the patients who had fair results. Proximal loop reflux did not occur, and we could detect no mechanical failure. Fats and fried food in excessive amounts are usually mentioned as apt to cause trouble. The results in the following six cases are definitely poor, and are worth closer review.

**Case 3**—A man, aged 58 at operation in 1943 complained of pain in the chest and left hypochondrium after meals. Two years later his abdomen was explored. No ulcer or other abnormality was found. His troubles persist but the pain is now chiefly in the back and he has some osteoarthritis of the spine. It is doubtful if his symptoms are digestive in origin, though there is no doubt that he is not a satisfied patient.

**Case 4**—A man, aged 57 at operation in 1944 complained of severe postcibal distress, including nausea and vomiting. During a fortnight's stay in hospital recently he appeared to be having very little trouble with his digestion. Investigations with a barium meal, test meal and glucose tolerance test disclosed no obvious cause for his reported symptoms.

**Case 5**—This patient, aged 20, had an antecolic gastrectomy with a rather long loop performed in 1943. The immediate result was satisfactory, but three months later he began to be increasingly troubled. Each meal particularly a large one or one containing fats, caused lassitude, distension and nausea so that he had to lie down. These would pass off in an hour to an hour and a half but occasionally he vomited fluid deeply stained with bile. Attacks of diarrhoea occurred. A barium meal emptied very rapidly indeed and caused some pooling in the small intestine. A test meal showed that there was no secretion of acid in the stomach. An indwelling Ryle's tube over twenty-four hours suggested that the meal left the stomach very rapidly, that the stomach then filled about half an hour later with a mixture of bile and pancreatic juices from the proximal loop and that his nausea came at the time when his stomach filled with fluid. It was decided that a laparotomy was justifiable since no simple remedies were of any avail and the patient was below weight and considerably disabled by these symptoms even though he managed to do his work.

FIG 3

FIG 4

An unduly long and dilated proximal loop was found. The anastomosis was unpicked and remade with a very short proximal retrocolic loop with a small valve. This brought considerable improvement. It seems reasonable to suggest, therefore, that the long proximal loop emptied badly into the gastric remnant, possibly through slight rotation and that food passed rapidly out of the remnant into the small intestine without a satisfactory mixture of bile and pancreatic juice.

**Case 6**—A man, aged 34 at operation in 1945 now complains of postcibal distress. He looks well and has gained weight. Full investigation at hospital showed no apparent abnormality and observation did not endorse his statement. He is in receipt of a pension for his gastric disorder, and has not attempted any work since the operation.

**Case 7**—A woman aged 42 at operation twenty months previously made satisfactory progress at first but in the last few months has complained of pain and flatulence after meals. Investigation revealed no apparent gastric cause of postcibal distress but showed the presence of gall stones. Cholecystectomy has since been performed, with relief of her symptoms.

**Case 8**—A man aged 56 at operation three years ago, was fit for two years but then developed oedema and ascites the cause of which was found to be cirrhosis of the liver.

Of the six patients in whom the results were classified as poor we can only be certain that two are suffering severe postcibal distress following their gastrectomy. This operation is still used, but is employed less than formerly. The loop is shorter and is stitched in position to the right of the gastric remnant to prevent the risk of rotation.

### Type III Post colic Anastomosis

Average period since operation	29 months
Number of operations	26
Operative mortality	Nil
Traced	23
Good results	16 (14 duodenal, 2 gastric)
Fair	4 (3 " 1 " )
Poor	1 (gastric)
Since died	2 (duodenal)
Causes of death	Cir accident coronary thrombosis
Untraced	(duodenal)
Male	Good at 6 months Changed address
Male	Left country after operation
Male	Fair at 3 months Changed address

In this procedure the anastomosis lies below the mesocolon, the edges of the aperture in this structure being stitched to the stomach. To enable this to be done the jejunum is not carried up to the lesser curve, which necessitates the construction of a smaller valve than that in the antecolic anastomosis.

Suction from an indwelling Ryle's tube in the immediate post operative period shows that the bile enters the stomach very rapidly. This suggested that it was the most suitable anastomosis to use if pressure in the duodenal stump was specially to be avoided.

During the period under review this anastomosis was employed in cases in which the antecolic anastomosis seemed to be inadvisable for the following reasons: (a) a very large transverse colon or mesocolon which, it was thought, might drag on the proximal loop, and (b) unsatisfactory closure of the duodenal stump due to extensive ulceration of the duodenum, which might lead to leakage if there was any pressure in the proximal loop.

**Post-operative Course**—The immediate post-operative course has been very satisfactory. The short loop has given no trouble, and as the whole anastomosis is below the mesocolon there has been no herniation of small intestine. We have not yet seen trouble from fibrosis of the mesocolon and compression of the anastomosis, which is suggested by Ogilvie (1947) as a possible sequel of this type of operation.

**Functional Result**—From the functional point of view the result seems satisfactory and the reduction in size of the valve does not appear to have had an adverse effect.

Sixteen are classified as good, four as fair functional results, and one (Case 9) as poor.

**Case 9**—A man aged 38 at operation three and a half years ago, has had considerable trouble from postcibal distress. This comes on immediately after a meal and consists of a feeling of distension and fatigue accompanied by sweating. It lasts about half an hour and then suddenly disappears often accompanied by a loud gurgle. He can always produce these attacks by taking fat and fried food and by moving about immediately after a meal. He can avoid them if he does not eat fats and if he rests for half an hour at the end of a meal. Barium meal examination shows rapid emptying of the stomach and some dilation of the small intestine. The proximal loop here was made rather unnecessarily long and it is probable that his trouble is due to delayed emptying of this loop.

### Type IV Billroth I Anastomosis

Average period since operation	23 months
Number of operations	47
Operative mortality	1 (gastric ulcer)
Cause of death	Pulmonary embolus
Traced	
Good	36 (1 duodenal, 35 gastric)
Fair	7 (1 " 6 " )
Poor	1 (duodenal)
Since died	2 (gastric)
Causes of death	Jaundice 18 months later apasitic
Untraced	Nil

**Post-operative Period**—In the immediate post-operative period this procedure has been entirely satisfactory, except in Case 10 described below. It has the merit of dispensing with the proximal loop, the foramen in the transverse mesocolon, and the duodenal stump, and thus avoids all the possible complications these may cause. From the point of view of safety, therefore, this technique appears to have advantages over any other type of anastomosis.

**Functional Result**—From the functional aspect we have found it as satisfactory as any other.

**Case 10**—A woman, aged 46 at operation in 1945 suffered from duodenal ulcer. At the operation it was noticed that the duodenal lumen was small consequently the anastomosis was a narrow one. An indwelling Ryle's tube suggested that the anastomosis did not become patent until the fifth day. She now complains of fullness during meals and has to take small ones. Barium meal examination shows a remnant which retains a barium meal for two and a half hours and empties slowly via a stenosed anastomosis.

This technique was used on two other patients suffering from duodenal ulcer, and one of them also shows a stomach which empties slowly, though it did not cause symptoms. There has been no sign of stenosis at the anastomosis in the gastric ulcer cases.

We are satisfied that as a treatment for gastric ulcer this anastomosis is sound, but the increased difficulty of mobilizing an ulcerated duodenum and the risk of late stenosis render it an unsuitable method for the patient with a duodenal ulcer.

### The Follow-up

Consideration of the cases whose results are listed as fair or poor leads to three conclusions: (1) That pain of the ulcer type is most unusual, and in the patients we have followed we have been unable to prove the presence of an anastomotic ulcer. (2) That the departure from a normal digestion is due to the incidence of what is described as "side effects" or postcibal distress. The symptoms of which the patients complain are nausea and, less often, vomiting, a feeling of distension, lassitude, sweating, and attacks of diarrhoea, and these come on at varying periods during or after a meal. (3) That fats and fried food are the articles of diet most likely to cause trouble.

### Side-effects

**Incidence and Severity**—If we consider that all patients in whom the results are classified as fair are suffering from

mild side effects then the incidence is 47 (22%) out of 216 followed up. But in these patients the side effects either are occasional or are preventable by eating only small or moderate meals. These restrictions do not interfere unreasonably with the life and habits of a normal person. From the ten patients whose results are classified as poor we can exclude two (Cases 7 and 8) whose trouble is due in one instance to gall-stones and in the other to cirrhosis of the liver. This leaves us with eight (36%) patients in whom side-effects due to the operation appear to be a serious problem.

**Causation and Treatment**—Various causes have been suggested in the literature, and we have examined our eight cases with these in mind. They have been investigated with barium meal, an indwelling Ryle's tube for twelve hours with a normal diet, blood counts, and sugar-tolerance curves. Three causes seem to us to fit certain of our patients and, moreover, to be due to the type of anastomosis used. They are proximal-loop filling, slow emptying of the stomach remnant and delayed emptying of the proximal loop.

**Proximal loop Filling**—Cases 1 and 2 come into this category. These patients may show one or more of the following symptoms coming on shortly after a meal: distension, lassitude, nausea, vomiting, sweating and a feeling of "bile rising in the back of the throat." Post-operative barium meal examination shows the meal entering a dilated proximal loop and gradually passing back through the stomach into the distal loop. They therefore empty slowly into the jejunum and the meal should have ample time to mix with the bile. It is noteworthy that diarrhoea does not seem to be associated with this group. Proximal-loop filling has occurred only with anastomosis of the afferent loop to the greater curve, a method which should not be used. In our patients who show proximal loop filling the symptoms are partly relieved by resting for half an hour after a meal and by avoiding excess fats and fried food.

**Slow Emptying of Stomach Remnant**—One patient (Case 10) who had had a Billroth I gastrectomy for duodenal ulcer comes into this category. The chief symptom is fullness coming on during a meal, this prevents further eating and takes some time to pass off. In this particular case a barium meal showed retention of the meal in the stomach remnant up to two and a half hours. The meal given was the usual fluid one and it is to be expected that any solid food would take even longer to leave the stomach. The cause of this delayed emptying is stenosis of the anastomosis in a Billroth I operation performed for a duodenal ulcer. This complication can be prevented in duodenal ulcer cases by performing an end-to-side anastomosis.

**Delayed Emptying of Proximal Loop**—This complication is mentioned by Lake (1948) as a possible cause of postcibal distress. If there is any obstruction to the outlet of the proximal loop the bile and pancreatic juice secreted during a meal will accumulate there and emptying of the loop across the anastomosis will be delayed. On the one hand distension of the proximal loop may be produced causing symptoms similar to proximal-loop reflux. On the other hand the food may proceed on down the jejunum unmixed with bile and pancreatic juice causing a tendency to fatty diarrhoea. The symptoms are therefore very similar to those of proximal-loop reflux with the addition of diarrhoea. Fatty diarrhoea does not seem to be a complication of proximal-loop reflux where the meal is well mixed with bile and pancreatic juices and empties slowly into the jejunum. In the obstructed-proximal-loop syndrome the meal may empty rapidly down the jejunum although the bile and pancreatic juices are detained at the upper end of the intestinal tract. Two patients (Cases 5 and 9) fit into this category.

In Case 5 the evidence is (a) Investigation shows that the proximal loop empties its contents into the stomach some time after the meal has passed through. (b) The patient obtains relief by vomiting a mixture of bile and pancreatic juice containing no food about one hour after the meal. (c) At operation the proximal loop was found to be dilated and

remaking the anastomosis has given considerable relief of his postcibal distress.

In Case 9 there is some clinical evidence that the distress is due to obstruction of a proximal loop. The patient notes that his distress is largely obviated if he lies on the left side and also that when he is experiencing the distress relief occurs suddenly and is accompanied by a loud gurgle in the upper abdomen.

Both these patients find fat and fried food very troublesome and should they eat much of this type of food they are liable to attacks of fatty diarrhoea. The trouble here is presumably either making too long a proximal loop or making one which at its junction with the stomach is slightly rotated or in some other way obstructed. If the symptoms are severe enough remaking of the anastomosis seems justifiable.

It is more difficult to ascertain the cause of the other cases of postcibal distress. Adlersberg and Hammerschlag (1947) divided their cases of this syndrome into early and late postprandial types, and this is a convenient arrangement. The early cases showing distress and coming on within an hour of taking a meal were considered to be typical of the so-called "dumping" stomach, whereas the late cases, coming on one to three hours after a meal, were thought to be due to hypoglycaemia. We have classified the remaining "poor" cases on these lines.

### The "Dumping" Stomach

This syndrome was described by Hertz (1913) as occurring after gastro-enterostomy. The term "dumping" stomach appears to have been first used by Mix in 1922 again in relation to gastro-enterostomy. In this paper the term is used to cover any cases of early postprandial distress for which no other explanation is available. Ingelfinger (1944) has reviewed the symptoms and possible causes of this syndrome. The symptoms include sweating, nausea, palpitations, and a feeling of weakness coming on toward the end of or just after a meal and lasting up to a hour. The cause of this is not clear; many suggestions as well as the original one of a rapidly emptying stomach have been made. It is difficult to believe that rapid emptying by itself is the cause of the trouble, because so many patients with no symptoms show extremely rapid emptying of a barium meal.

Glaessner (1940) considered that the symptoms might be due to hyperglycaemia, and Zollinger and Hoerr (1947) thought that rapid absorption of sugar was the cause. Custer *et al* (1946) blamed the sudden mechanical distension of the jejunum due to rapid emptying of the stomach.

This syndrome in a mild degree is seen in some of our cases which are listed as "fair" functional results. It has been observed after a Billroth I anastomosis, and H. Daintree Johnson (1948—personal communication) has reported similar symptoms following simple vagotomy with out gastro-enterostomy. It is therefore not necessarily due to the stomach emptying straight into the jejunum when an end-to-side anastomosis is made. We agree with the usual view that this anastomosis is less likely to be followed by dumping symptoms if it has a small stomach and an adequate valve.

We have placed two of our "poor" cases (Nos 4 and 1) in this ill-defined category.

### Hypoglycaemia

Barnes (1947) described several cases in which hypoglycaemia appeared to be the cause of postcibal distress. The symptoms begin one hour or more after a meal and the patient experiences weakness, giddiness, and nausea; sweating and pallor may be noted.

After careful investigation none of our poor results can be attributed to hypoglycaemia. Questioning has revealed

that a few times in the year two patients listed under "fair" results have had attacks that are suggestive of hypoglycaemia, and their glucose tolerance curves, though not conclusive, lend support to this belief. Apart from this there is nothing to suggest that hypoglycaemia is either a frequent or a troublesome factor in producing postcibal distress, and we find nothing to support Gilbert and Dunlop's (1947) view that it is the essential cause of that distress.

In this series the symptoms usually begin during or shortly after a meal, at a time when the blood sugar curve is high. In addition the symptoms are exacerbated, not alleviated, by taking meals with a high fat content.

### Neurosis

We have been loath to attribute post-gastrectomy symptoms to neurosis, though there is some evidence of this in Cases 4 and 6. While under observation in the ward they did not complain of postcibal distress, nor did they show the objective phenomena, such as sweating, which are associated with this condition. They probably have occasional symptoms. These two patients come under the ill-defined heading of the 'dumping' stomach, but both are in receipt of a pension on account of their gastric disability which may well be a factor in their symptomatology.

There is one other patient (Case 3) whose chief post-operative symptom is backache. Neither his symptoms nor investigations suggest that his alimentary tract is the cause of the trouble.

### Conclusions

The review of this series has brought out the following points:

That the operation of partial gastrectomy for simple ulcer carries a reasonably low mortality. In this series it was 2%.

That in the main the patients who have had a partial gastrectomy for ulcer are satisfied. 73% are symptom-free and 22% have slight symptoms which are not severe enough to make them dissatisfied.

Approximately 5% either have a poor functional result or are dissatisfied. Investigation of this group is worth while in some cases, faults due to the technique of the operation are disclosed and can be remedied. Intercurrent disease may be the cause in other cases.

That the more troublesome and chronic the original ulcer the more tolerant is the patient of minor functional disturbances in his post-gastrectomy result.

With the exception of anastomosis of the afferent loop to the greater curve which leads to a high incidence of proximal loop filling there is nothing to choose between the functional results of the other three anastomoses employed.

The long proximal loop needed in the antecolic operation is more likely to lead to complications than the short loop used in the retrocolic operation. The Billroth I anastomosis is probably the safest of all as it has no afferent loop. Owing to the risk of stenosis this is not a suitable anastomosis after gastrectomy for duodenal ulcer.

That in this series there is no evidence to support the view that gastrectomy for duodenal ulcer gives worse results than for gastric ulcer. 80% of operations for duodenal ulcer were classified as good, as opposed to 58% for gastric ulcer. In both types of ulcer the incidence of poor results was 5%.

## THE STREPTOMYCIN-SULPHADIAZINE TREATMENT OF UNDULANT FEVER

BY

L. F. SCOWEN, M.D., F.R.C.P.

Physician St Bartholomew's Hospital, Reader in Medicine  
University of London

AND

L. P. GARROD, M.D., F.R.C.P.

Bacteriologist St Bartholomew's Hospital, Professor of  
Bacteriology, University of London

The results of chemotherapy in undulant fever have hitherto been disappointing. *Brucella abortus* is sensitive to sulphonamides, but a full course of treatment with these drugs, though often of temporary benefit, does not usually eradicate the infection. Possibly sulphadiazine together with blood transfusions as recently advocated by Holmes and Hughes (1948), may give better results. Penicillin is useless owing to the insensitivity of the organism. On the other hand, *Br. abortus* is sensitive to streptomycin, its growth being inhibited by from 0.5 to 3.75 µg per ml (Report, 1946), a finding well within limits compatible with successful treatment.

Such *in vitro* findings accurately reflect the therapeutic capacity of penicillin, but in connexion with streptomycin they are sometimes misleading and the two principal diseases which have not responded to streptomycin treatment in accordance with expectation on these grounds are typhoid fever and undulant fever. Earlier reports from the U.S.A. (Reimann et al. 1945; Report 1946; Nichols and Herrell, 1946) all based on the treatment of a substantial number of patients, usually with full doses given for what should be an adequate period are unanimous in their disappointment with the results. Some patients have not appeared to respond in any way, fever continuing and blood culture remaining positive even during the course. Others have improved temporarily but few have apparently been cured.

When two chemotherapeutic agents of partial efficacy are available it is likely that they will have an additive if not a synergic effect when administered together. Hence it was clearly indicated that a trial should be made of the combined effect of streptomycin and sulphadiazine. Eisele and McCullough (1947) claim to have reported the first case so treated. It is very fully described and the result seems highly significant. The patient was severely ill and his blood culture was regularly positive during earlier courses of treatment which included periods during which streptomycin and sulphadiazine were administered separately. Only when the two drugs were given together, at the rate of 6 and 12 g. respectively per day for ten days was there a response. This was complete, the temperature reaching normal levels at the end of this short course and remaining there. No relapse occurred during the ensuing 17 months. Six cases were treated by Puliski and Amspacher (1947) who recommend that 0.5 g. of streptomycin and 6 g. of sulphadiazine should be given four-hourly for fourteen days. In one patient the treatment was a complete failure. It is mentioned that *Brucella* could not be cultivated from the blood, and the evidence on which the diagnosis was based is not given. In the other five patients, four of whom had positive blood cultures, treatment was successful. Evidently the six cases described by Puliski and Seeley (1948) are the same, and in this further paper it is recorded that two patients had recurrences after six and twelve weeks respectively. It is to be noted that the dose of sulphadiazine advocated by these authors is only half that used by Eisele and McCullough.

We have had the opportunity of testing this treatment in two severe cases of undulant fever—one at an early and one in a later state. The regime decided on was 2 g of sulphadiazine four-hourly (i.e., 12 g daily) by mouth, and 1 g of streptomycin eight-hourly (3 g daily) by intramuscular injection, continued for fourteen days. In both cases the treatment seems to have been completely successful.

### Case 1

A surgeon dentist aged 53 was admitted to hospital on May 9, 1948. Eight months ago he had noticed vague ill health: he was easily tired and exhausted, and was losing weight. This ill-health was followed in the course of a few weeks by an attack of gastro enteritis which lasted for ten days. He recovered from the gastro enteritis but vague ill-health remained. Investigations at that time with barium meal and enema revealed no abnormality. This state of affairs continued until five months ago, when he developed pain in the ears and fever. With treatment the pain in the right ear subsided but not in the left: the left mastoid was explored and drained. After three weeks convalescence he went to Cornwall to recuperate. A few days later he developed a sudden rigor, with high fever, and returned to London. The upper respiratory tract was investigated carefully and both antra were punctured, with negative results. Finally the left mastoid was explored again but no abnormality was discovered. The fever continued and further investigation revealed at this time a positive agglutination for *Br. abortus*. For the next two months fever continued to undulate, as can be seen on the accompanying Chart, and was uninfluenced by full courses of both sulphamezathine and penicillin.

During the last week before admission to hospital the fever had recurred rather more severely, the general condition deteriorated dramatically, and he developed some jaundice and ascites.

On May 9, 1948, the day of admission to this hospital he was critically ill with high fever, marked prostration, and with periods of mild delirium. The agglutinin titre for *Br. abortus* was 1 in 12,500 with a marked pro zone phenomenon. Blood cultures taken at that time were sterile. The blood count showed a Hb of 86% with a white count of 12,600, polymorphs 6,300, lymphocytes 4,158, large mononuclears 1,008, eosinophils 1,008, basophils 126. The ascites was tapped and a slightly opalescent straw coloured fluid removed with a protein content of 0.48 g per 100 ml and a cellular content of 248 per cmm of which 104 were polymorphonuclear and the remainder mononuclear cells. The severity of the condition precluded any further investigation as it was felt that treatment must be started immediately.

Treatment was begun on May 10 with 1 g of streptomycin intramuscularly every eight hours and 2 g of sulphadiazine by mouth every four hours. The urine was kept alkaline by the administration of sodium bicarbonate. After three days the patient was afebrile and the jaundice was disappearing. He remained afebrile but treatment had to be interrupted on the twelfth day, as haematuria began. No further chemotherapy was used and the patient has remained afebrile during the last six months. The splenomegaly which was present on admission slowly regressed and the spleen has not been palpable for the last two months. The agglutinin titre for *Br. abortus* on June 14 had fallen to 1 in 1,250, and has been found recently (Nov. 27) to be 1 in 500.

Ascites has remained ever since its original occurrence and has required paracentesis every two to three weeks. The plasma protein on July 6 showed an albumin of 2 g per 100 ml and a globulin of 4.5 g per 100 ml. This ratio was brought back to normal by intravenous serum albumin, but in spite of this, a high protein intake, and injection of liver extract ascites has continued to recur.

This patient was known to have had splenomegaly for many years, and the ascites is considered to be due to an exacerbation of his primary condition during the course of the present superimposed long febrile illness.

### Case 2

A nurse aged 35 was admitted to hospital on Sept. 16, 1948, complaining of abdominal pain and fever. For many years she had been subject to attacks of vague abdominal pain in the right iliac fossa, with occasional attacks of slight diarrhoea. Appendicectomy had been performed ten years previously, but the appendix showed no lesion. Fourteen days before admission vague abdominal pain had begun and she was noticed to have an evening pyrexia. During these fourteen days there was intermittent fever with temperatures up to 103 to 104° F (39.4 to 40° C) in the evenings and slight rigors. Examination showed no physical signs of abnormality but the blood count had shown a leucopenia of 5,200 of which 64% were polymorphonuclears, and a sedimentation rate of 9 mm in one hour. A positive agglutination for *Br. abortus* had been discovered during that time.

On admission to hospital there was pyrexia as is shown on the chart but physical examination was still negative. An agglutination test gave the following result:

	1:25	1:50	1:125	1:250	1:500	1:1,250	1:2,500	1:5,000
<i>Br. abortus</i>	—	—	+	+	+	+	Trace	—
<i>Br. melitensis</i>	—	—	Trace	—	—	—	—	—

Blood cultures taken at this time became positive on Sept 30, and on the same day the spleen became palpable for the first time

Treatment with 1 g of streptomycin eight-hourly intramuscularly, and 2 g of sulphadiazine four hourly by mouth, was begun on Sept 24 and continued for fourteen days. On the sixth day of treatment fever began to fall. By the end of treatment the patient was afebrile, but immediately after its cessation occasional pyrexia up to 99° F (37.2° C) recurred, but this disappeared without any further treatment and the fever has not recurred up to the present time over the last two months. There have however, been during this time several attacks of abdominal discomfort to which she has been prone for the last few years. The agglutination for *Br abortus* had fallen to 1 in 1250 on Oct 19 and to 1 in 500 on Nov 26. The splenomegaly had disappeared two weeks after treatment was completed.

**Characters of *Br abortus***—This organism was found in only one of many tubes after incubation for twelve days in 10% CO<sub>2</sub>. On first isolation it was fully CO<sub>2</sub>-sensitive, but after four subcultures growth, poor at first but later fairly profuse, was obtained in a normal atmosphere. The sensitivity to streptomycin was tested by preparing slopes of beef heart extract peptone agar of pH 7.4 containing falling concentrations of streptomycin and inoculating them with a 2-mm loopful of an approximate 1 in 500 dilution of a broth culture. The minimum inhibitory concentration was found to vary with the atmosphere as follows

	Minimum Inhibitory Concentration	Maximum Concentration Permitting Growth
No added CO <sub>2</sub>	0.5 µg per ml	0.25 µg per ml
10% CO <sub>2</sub>	1.5	1.0
25% CO <sub>2</sub>	2.5	2.0

These differences are evidently due to the alteration in pH of the medium produced by CO<sub>2</sub>. It is well recognized that even a slight shift towards the acid side diminishes the activity of streptomycin. The findings indicate that this strain is fully streptomycin sensitive.

#### Comment

Of these two cases, one was of several months' duration and the other was recent. Both responded to combined treatment with streptomycin and sulphadiazine, the former with a fall in temperature to normal within three days, the second somewhat more gradually, the temperature reaching normal only at the end of the course. They have now been afebrile for six and two months respectively. These observations confirm American reports of the efficacy of this treatment. We do not claim that the optimum scheme of dosage has been defined, but from the successful results in these two cases and the ease described by Eisele and McCullough, all of which were given 12 g of sulphadiazine daily, contrasted with the relapses in Pulaski and Amspacher's series, it seems likely that the larger dose is necessary.

We are indebted to the Streptomycin Clinical Trials (Non-Tuberculous Conditions) Committee of the Medical Research Council for the streptomycin used in the treatment of these patients, and to Mr Daniel T. Davies for earlier clinical details of Case 1.

## THE TREATMENT OF ANURIA

BY

D A K BLACK, MD, MRCP

AND

S W STANBURY, MB, MRCP.

(From the Department of Medicine the Royal Infirmary, Manchester)

Although anuria is not a common emergency in medical practice it is an important one, partly because two of the commoner forms of anuria are iatrogenic and partly because persistent anuria is surely followed by death. The causes and treatment of anuria have alike been illuminated in the past few years, the one by important advances in our knowledge of renal function, the other by the painstaking ingenuity of workers like Kolff and Alwall in devising means of maintaining excretion during what is hoped may be a temporary suspension of renal activity.

Suppression of urine has been observed in so many different disease states that it is doubtful whether the same underlying mechanism can be present in all. Sometimes as in acute nephritis or bilateral urinary obstruction, there is a clear background of morbid anatomy to account for the anuria. Sometimes, as in patients with shock or dehydration, the anuria is just as clearly the result of the patient's general state, and the kidneys cannot be primarily incriminated. The greatest interest, however, attaches to those types of urinary suppression, such as transfusion kidney and the crush syndrome, in which the ultimate cause is extrarenal but the kidneys show definite morbid anatomical changes. Further examples of anuria, not primarily renal, in which there are renal changes of doubtful significance may be found in sulphonamide anuria, blackwater fever, anuria following abortion, and poisoning with uranium or mercury salts.

#### Pathogenesis of Anuria

Leaving aside the primary aetiology of anuria, which concerns prophylaxis, we come to the mechanism or mechanisms by which anuria may be produced. It is here if anywhere, that we may expect to find clues to the rational treatment of the established condition. We shall exclude from present consideration anuria associated with a definite pre-existing renal lesion or gross urinary tract obstruction and assume that we are dealing with a kidney which is normal so far as the general arrangement of nephrons is concerned. In the normal kidney the raw material of urine is formed in the glomeruli, and the tubules have the function of transmitting glomerular filtrate to the renal pelvis, modifying it on the way so that the dilute ultrafiltrate of plasma becomes the concentrated and highly selected final urine. A failure of the glomeruli to form filtrate and a failure of the tubules to transmit it to the right place, would alike be followed by anuria. The possibilities for impaired function of glomeruli and tubules can be considered separately.

Normally the glomeruli filter off about one-fifth of the plasma which is presented to them, and so far as is known this process is a purely physical one, influenced only by the amount and pressure of glomerular blood flow and by the physical permeability of the glomerular membrane. A loss of glomerular permeability need not be seriously considered as a cause of complete anuria, but alterations in the supply of blood to the glomeruli are obviously important. Van Slyke (1948) has reviewed extensive experimental work carried out on renal function during shock, when blood volume and cardiac output are diminished the renal

blood flow falls to a much greater extent than does the cardiac output. The dog's kidney can survive experimental deprivation of its blood supply for as long as two hours a time which causes irreversible renal damage in the rabbit. Badenoch and Darmady (1947) express the opinion that more than six hours occlusion might be required in man to cause irreversible renal damage. Results obtained in man by clearance techniques show very low renal blood flow after haemorrhage (Black *et al.* 1941) and during surgical shock (Lauson *et al.*, 1944).

Until recently a partial or complete "renal shutdown" was the only form of circulatory upset that had to be considered, but Trueta, Barclay, and their colleagues (1947) have shown that in rabbits a shunting of the circulation within the kidney may occur so that the glomeruli of the renal cortex are no longer fully perfused. They found anatomical and radiological evidence of an alternative circulatory pathway through large glomeruli in the boundary zone of the kidney and the medullary vasa recta. Although the vessels involved in the Barclay-Trueta shunt can be demonstrated in man, direct proof of the occurrence of the shunt in man has not yet been obtained, and the effect of the shunt on renal function is also not fully established. While it is certain that the shunt will not explain all the unsolved problems of renal disease, the possibility of its presence cannot be neglected in any of them. When a technique has been worked out for determining in the intact patient whether the shunt is in operation or not, then it may be found that some types of anuria, such as reflex anuria, which are difficult to explain in any other way involve the presence of a shunt.

There are, however, several types of anuria, such as sulphonamide and mercurial anuria, in which it is hard to conceive of the renal damage as being due to suppression of glomerular filtration. Damage to the renal tubules could cause anuria in several ways—by blockage, by excessive reabsorption, or even by direct communication between the distal tubule and the blood stream. Tubular blockage of significant degree may be found in multiple myeloma, in transfusion kidney, and in sulphonamide anuria, though here the blockage may be more of pelvis and ureter than of the tubule proper. It is exceptional, however, for tubular obstruction to be universal, and the general opinion is that simple blockage will not account for complete anuria in such conditions as blackwater fever (Macgrath, 1944).

More important probably than actual blockage of the tubules is damage to the tubule epithelial cells of such a nature as to destroy the selective permeability on which the formation of urine from glomerular filtrate depends. The changes which have been observed in the tubule cells in functional renal failure range from hyaline droplet change to complete necrosis and desquamation, followed later by regeneration. The lack of constancy in the histological picture, and the known liability of the renal tubules to early post-mortem change, have led to relative neglect of the part played by the tubules in the pathogenesis of oliguria and anuria. However, they have been restored to full prominence by the work of Bywaters (1941, 1944) on the crush syndrome, and of Lucke (1946) on the post-traumatic syndrome, which he designates 'low nephron nephrosis'. Moon (1948) accepts Lucke's views on the importance of tubular lesions in renal damage following "shock" but denies that the lesions are limited to the distal segment of the nephron. Shaw Dunn used the telling metaphor of "a morass" to describe the state of affairs in which fluid leaks freely back from damaged tubules into the peritubular blood vessels, he was the first to demonstrate direct communications between tubules and veins similar to those found in experimental phosphate poisoning (Dunn *et al.* 1941).

Summarizing present views on the pathogenesis of anuria, it may be said that emphasis in this country has generally been laid on circulatory changes, Macgrath *et al.* (1945) put forward the unifying hypothesis of "renal anoxia" to account for many types of functional renal failure, and this view has derived support from the discovery of unsuspected possibilities of disturbance in the renal circulation. On the other hand, in a recent American symposium on "renal insufficiency in the shock syndrome" Moon (1947) and others emphasized the tubular damage, so much more impressive anatomically than anything that can be seen in the glomeruli of such kidneys. These two views represent a difference in emphasis rather than a complete contradiction, for any serious impairment of the circulation to the glomeruli is likely to cause damage to the tubules, whose blood supply is dependent on glomerular integrity, and we might even hazard a guess that in the long run both circulatory and tubular factors will be proved important, though in varying degree from patient to patient. The past history of renal physiology should warn us against the "either-or" type of mental approach to this fascinating and versatile organ.

### Methods of Treatment

The sudden occurrence of anuria after operation or transfusion may produce a mood of therapeutic desperation in which all sorts of procedures have been carried out, from dry cupping to decapsulation. Since urine flow may be re-established quite spontaneously at any time it is impossible to assess the various possible modes of therapy by the usual method of considering their results, for no single centre is likely to encounter enough anuric patients to do a controlled trial of even one method of therapy. Since reliable conclusions cannot be drawn from the apparent results of therapy, we can only consider the proposed ways of treatment in relation to our present information on the pathogenesis of anuria.

In a general way the objectives of treatment are to restore urine flow, and in default of this to prevent such distortion of the patient's internal environment that he will succumb before urine formation has been effectively restored. Believers in circulatory changes as the usual cause of anuria will approach the task of restoring urine flow with greater optimism than those who lay stress on tubular degeneration, for it is less likely that tubular lesions will be much influenced by any form of active therapy. The vasoconstrictor nerves to the kidney are sympathetic, and Barclay and Trueta found that splanchnic section would prevent the development of the renal shunt in rabbits. On this basis, anuria has been treated by paravertebral block, or by high spinal analgesia as a more certain way of blocking the entire sympathetic supply to the renal vessels. Successes and also failures have been reported with both methods, but it is never possible to exclude an opportune spontaneous recovery of urine flow. Nevertheless, it would seem justifiable to attempt splanchnic block, and the use of sympatholytic drugs such as tetraethylammonium bromide or dibenamine might be considered as an alternative to the use of local or spinal analgesia. Although such procedures may lower blood pressure for a short time they can safely be applied in patients without peripheral circulatory failure, and in a proportion of cases so treated there has been apparent success.

The use of alkalis and of diuretics, also designed to restore urine flow, is much more questionable. Mercurial diuretics would be ineffective on the "circulatory theory" and harmful on the "tubular damage" theory. Osmotic diuretics such as sodium sulphate are commonly used in surgical anuria, and Olson and Nechles (1947) report favourably on the use of sodium sulphate in dogs with

anuria secondary to experimental burns Sodium sulphate acts osmotically by diminishing the proportion of glomerular filtrate which is reabsorbed, and it is difficult to see how it can be effective unless some degree of glomerular filtration is already established The cessation of urine flow after experimental burns is obviously different in mechanism from other types of anuria and the results of Olson and Neeheles cannot be generally applied Sodium sulphate may have a place in the treatment of extreme oliguria but in complete anuria any addition of osmotically active substances to the body fluids is risky Treatment with alkalis, although it may be effective prophylactically in preventing haemoglobin precipitation, cannot destroy casts already present in the tubules, and in any event tubular blockage is not considered an important cause of anuria In the presence of anuria even small doses of alkalis are retained, and alkalosis is a very real danger The only indication for giving alkalis in anuria is the presence of acidosis and in such cases correction of the acidosis may be followed by the restoration of urine flow (van Slyke, 1948)

While attempts to restore urine flow are being made attention has also to be directed to the prevention so far as possible of clinical and biochemical deterioration On the 'tubular damage' theory conservative measures are the sensible ones to adopt, and this is far from being therapeutic nihilism for the kidneys in fatal anuria commonly show extremely active regeneration of tubular cells in injured areas (Coreoran and Page, 1947), giving hope that artificial maintenance of excretory and homeostatic function for a longer period might have allowed recovery Moreover, correct maintenance therapy demands an attention to important detail for which "doing nothing" is the least suitable epithet imaginable

#### Protein Metabolism

Although no one now believes that urea itself is responsible for the symptoms of uraemia, the estimation of urea or of non-protein nitrogen can still be used as a convenient measure of the extent to which the body is failing to get rid of harmful end-products of protein metabolism Maintenance therapy in anuria should aim both at reducing the amount of protein which is being broken down and at eliminating nitrogenous and other waste products by extrarenal channels

Nitrogen catabolism is at its lowest when the intake of food protein is minimized and the calorie needs of the body are fully supplied by carbohydrate and fat Borst (1948) has used a butter-sugar diet which has a high calorie value and a negligible protein content, the urinary nitrogen falls to very low levels in normal people on this type of diet Such a diet is, however, remarkably unpalatable, and would not seem to offer any corresponding advantage over a more varied diet containing about 30 g of protein per day and 2,500 calories, made up mostly in fat and carbohydrate So long as the amount is small it does not seem greatly to matter whether the irreducible minimum of protein for catabolism comes from the food or from the tissues, but it has to be remembered that infection may increase the rate of tissue breakdown, and Borst (1948) records a case in which infection seemed clearly responsible for the very rapid development of uraemia There is therefore a clear indication for the active treatment of any infective process in an anuric patient as part of the programme for cutting down the breakdown of protein Another likely cause of accelerated protein catabolism is disturbance of salt-and-water metabolism, and the fluid balance demands careful attention for this reason, as well as in its own right As a general approximation, in a temperate climate the urine accounts for about half of our total fluid loss, suppression of urine

therefore calls for some restriction of the fluid intake, and so long as no urine is being passed a litre of fluid a day is sufficient for any patient who is not visibly sweating and has no fever Restriction of salt intake is even more important, for in the absence of urine formation the only significant remaining channel of salt loss is the sweat, and sweat has a salt content much lower than plasma or extracellular fluid When the kidneys fail the body has no means of excreting salt in hypertonic solution, and so cannot protect itself from being pickled by excessive salt in the diet A "salt-free" diet, in the conventional sense, should accordingly be used The essential value of such conservative treatment is to prolong the period of survival in total anuria and so allow more time for repair of kidney tubular structure and function

#### Elimination of Waste Products

As means towards the same end many methods have been tried for getting rid of waste products by routes other than the kidneys Sweating and purging are inefficient ways of lowering the blood urea, because the strain imposed on the patient and the amount of fluid lost are out of proportion to any decrease in the urea content of the body which can be achieved A more helpful approach is the continuous dialysis of blood in a "cellophane" tube against some form of Ringer-Loeck solution, as alternatives to a cellophane tube the peritoneum and the mucosa of isolated loops of bowel have been used as dialysing membranes Kolff (1947) gives an extended account of the use of methods of this type, and it is quite clear that in special clinics these methods are safe and can be useful in getting rid of significant amounts of urea and presumably of other waste products On the debit side, these methods are far from being generally applicable with safety, for they involve the use of heparin when blood is the perfusing substance, or of large amounts of aseptic solutions when the body cavities are used for perfusion An isolated loop of bowel avoids some of these troubles but it is likely to become atonic and even to rupture An ingenious method described by Maluf (1948) avoids the necessity for heparin or any operative procedure or the use of aseptic irrigating fluid

In this method a triple Miller-Abbott tube is introduced until the balloon lodges in the caecum, slightly hypertonic sodium sulphate solution is run into the duodenum and withdrawn from the terminal ileum the rate of flow aimed at being 20-30 ml per minute Early reports of the use of this type of method are now appearing (Oppenheimer and Rosenak, 1948, Odell and Ferris 1948) and we have ourselves had the opportunity of using it in one patient, whose case history is appended Like other users of the method we have encountered two main practical difficulties First it is difficult to get the tube into the right place without provoking nausea Secondly, we found it quite impossible to get back the solution at anything like the recommended rate, for any tube which can reasonably be passed is much too fine to allow adequate suction of large amounts of fluid The first difficulty can be overcome only by patience, and by letting the tube stay down once it is down, avoiding the need for frequent manipulation The second difficulty resolves itself with some discomfort to the patient, by the passage of copious watery stools It would seem reasonable, instead of trying to suck the fluid all the way back to the mouth, to let it flow on through a simple duodenal tube and withdraw it by a wide rectal tube Although we had these initial difficulties it was possible to rid the body of 15 g of urea, this amount is much larger than that recorded by Odell and Ferris, using the same principle This may be partly because they employed only a modified Ringer solution, while we followed

blood flow falls to a much greater extent than does the cardiac output. The dog's kidney can survive experimental deprivation of its blood supply for as long as two hours, a time which causes irreversible renal damage in the rabbit. Badenoch and Darmady (1947) express the opinion that more than six hours occlusion might be required in man to cause irreversible renal damage. Results obtained in man by clearance techniques show very low renal blood flow after haemorrhage (Black *et al.* 1941) and during surgical shock (Lauson *et al.*, 1944).

Until recently a partial or complete "renal shutdown" was the only form of circulatory upset that had to be considered, but Trueta, Barclay, and their colleagues (1947) have shown that in rabbits a shunting of the circulation within the kidney may occur so that the glomeruli of the renal cortex are no longer fully perfused. They found anatomical and radiological evidence of an alternative circulatory pathway through large glomeruli in the boundary zone of the kidney and the medullary vasa recta. Although the vessels involved in the Barclay-Trueta shunt can be demonstrated in man, direct proof of the occurrence of the shunt in man has not yet been obtained, and the effect of the shunt on renal function is also not fully established. While it is certain that the shunt will not explain all the unsolved problems of renal disease, the possibility of its presence cannot be neglected in any of them. When a technique has been worked out for determining in the intact patient whether the shunt is in operation or not, then it may be found that some types of anuria, such as reflex anuria, which are difficult to explain in any other way involve the presence of a shunt.

There are, however, several types of anuria, such as sulphonamide and mercurial anuria, in which it is hard to conceive of the renal damage as being due to suppression of glomerular filtration. Damage to the renal tubules could cause anuria in several ways—by blockage, by excessive reabsorption or even by direct communication between the distal tubule and the blood stream. Tubular blockage of significant degree may be found in multiple myeloma, in transfusion kidney, and in sulphonamide anuria, though here the blockage may be more of pelvis and ureter than of the tubule proper. It is exceptional, however, for tubular obstruction to be universal, and the general opinion is that simple blockage will not account for complete anuria in such conditions as blackwater fever (Macgrath 1944).

More important probably than actual blockage of the tubules is damage to the tubule epithelial cells of such a nature as to destroy the selective permeability on which the formation of urine from glomerular filtrate depends. The changes which have been observed in the tubule cells in functional renal failure range from hyaline droplet change to complete necrosis and desquamation, followed later by regeneration. The lack of constancy in the histological picture, and the known liability of the renal tubules to early post-mortem change, have led to relative neglect of the part played by the tubules in the pathogenesis of oliguria and anuria. However, they have been restored to full prominence by the work of Bywaters (1941, 1944) on the crush syndrome, and of Lucke (1946) on the post-traumatic syndrome, which he designates "low nephron nephrosis". Moon (1948) accepts Lucke's views on the importance of tubular lesions in renal damage following "shock" but denies that the lesions are limited to the distal segment of the nephron. Shaw Dunn used the telling metaphor of "a morass" to describe the state of affairs in which fluid leaks freely back from damaged tubules into the peritubular blood vessels; he was the first to demonstrate direct communications between tubules and veins similar to those found in experimental phosphate poisoning (Dunn *et al.*, 1941).

Summarizing present views on the pathogenesis of anuria, it may be said that emphasis in this country has generally been laid on circulatory changes, Macgrath *et al.* (1945) put forward the unifying hypothesis of "renal anoxia" to account for many types of functional renal failure, and this view has derived support from the discovery of unsuspected possibilities of disturbance in the renal circulation. Osmotic diuretics such as sodium sulphate are commonly used in surgical anuria, and Olson and Necheles (1947) report favourably on the use of sodium sulphate in dogs with

anuria secondary to experimental burns Sodium sulphate acts osmotically by diminishing the proportion of glomerular filtrate which is reabsorbed, and it is difficult to see how it can be effective unless some degree of glomerular filtration is already established The cessation of urine flow after experimental burns is obviously different in mechanism from other types of anuria, and the results of Olson and Necheles cannot be generally applied Sodium sulphate may have a place in the treatment of extreme oliguria but in complete anuria any addition of osmotically active substances to the body fluids is risky Treatment with alkalis, although it may be effective prophylactically in preventing haemoglobin precipitation, cannot destroy casts already present in the tubules, and in any event tubular blockage is not considered an important cause of anuria In the presence of anuria even small doses of alkalis are retained, and alkalosis is a very real danger The only indication for giving alkalis in anuria is the presence of acidosis and in such cases correction of the acidosis may be followed by the restoration of urine flow (van Slyke, 1948)

While attempts to restore urine flow are being made attention has also to be directed to the prevention so far as possible of clinical and biochemical deterioration On the "tubular damage" theory conservative measures are the sensible ones to adopt, and this is far from being therapeutic nihilism for the kidneys in fatal anuria commonly show extremely active regeneration of tubular cells in injured areas (Coreoran and Page, 1947), giving hope that artificial maintenance of excretory and homeostatic function for a longer period might have allowed recovery Moreover, correct maintenance therapy demands an attention to important detail for which "doing nothing" is the least suitable epithet imaginable

#### Protein Metabolism

Although no one now believes that urea itself is responsible for the symptoms of uraemia, the estimation of urea or of non-protein nitrogen can still be used as a convenient measure of the extent to which the body is failing to get rid of harmful end-products of protein metabolism Maintenance therapy in anuria should aim both at reducing the amount of protein which is being broken down and at eliminating nitrogenous and other waste products by extra-renal channels

Nitrogen catabolism is at its lowest when the intake of food protein is minimized and the calorie needs of the body are fully supplied by carbohydrate and fat Borst (1948) has used a butter-sugar diet which has a high calorie value and a negligible protein content, the urinary nitrogen falls to very low levels in normal people on this type of diet Such a diet is, however, remarkably unpalatable, and would not seem to offer any corresponding advantage over a more varied diet containing about 30 g of protein per day and 2,500 calories, made up mostly in fat and carbohydrate So long as the amount is small it does not seem greatly to matter whether the irreducible minimum of protein for catabolism comes from the food or from the tissues, but it has to be remembered that infection may increase the rate of tissue breakdown, and Borst (1948) records a case in which infection seemed clearly responsible for the very rapid development of uraemia There is therefore a clear indication for the active treatment of any infective process in an anuric patient as part of the programme for cutting down the breakdown of protein Another likely cause of accelerated protein catabolism is disturbance of salt-and-water metabolism, and the fluid balance demands careful attention for this reason, as well as in its own right As a general approximation, in a temperate climate the urine accounts for about half of our total fluid loss suppression of urine

therefore calls for some restriction of the fluid intake, and so long as no urine is being passed a litre of fluid a day is sufficient for any patient who is not visibly sweating and has no fever Restriction of salt intake is even more important, for in the absence of urine formation the only significant remaining channel of salt loss is the sweat, and sweat has a salt content much lower than plasma or extracellular fluid When the kidneys fail the body has no means of excreting salt in hypertonic solution, and so cannot protect itself from being pickled by excessive salt in the diet A "salt-free" diet, in the conventional sense should accordingly be used The essential value of such conservative treatment is to prolong the period of survival in total anuria and so allow more time for repair of kidney tubular structure and function

#### Elimination of Waste Products

As means towards the same end many methods have been tried for getting rid of waste products by routes other than the kidneys Sweating and purging are inefficient ways of lowering the blood urea, because the strain imposed on a patient and the amount of fluid lost are out of proportion to any decrease in the urea content of the body which can be achieved A more helpful approach is the continuous dialysis of blood in a "cellophane" tube against some form of Ringer-Locke solution, as alternatives to a cellophane tube the peritoneum and the mucosa of isolated loops of bowel have been used as dialysing membranes Kolff (1947) gives an extended account of the use of methods of this type, and it is quite clear that in special clinics these methods are safe and can be useful in getting rid of significant amounts of urea and presumably of other waste products On the debit side, these methods are far from being generally applicable with safety, for they involve the use of heparin when blood is the perfusing substance, or of large amounts of aseptic solutions when the body cavities are used for perfusion An isolated loop of bowel avoids some of these troubles, but it is likely to become atonic and even to rupture An ingenious method described by Maluf (1948) avoids the necessity for heparin or any operative procedure, or the use of aseptic irrigating fluid

In this method a triple Miller-Abbott tube is introduced until the balloon lodges in the caecum, slightly hypertonic sodium sulphate solution is run into the duodenum and withdrawn from the terminal ileum, the rate of flow aimed at being 20-30 ml per minute Early reports of the use of this type of method are now appearing (Oppenheimer and Rosenak, 1948, Odel and Ferris 1948) and we have ourselves had the opportunity of using it in one patient, whose case history is appended Like other users of the method we have encountered two main practical difficulties First it is difficult to get the tube into the right place without provoking nausea Secondly, we found it quite impossible to get back the solution at anything like the recommended rate, for any tube which can reasonably be passed is much too fine to allow adequate suction of large amounts of fluid The first difficulty can be overcome only by patience, and by letting the tube stay down once it is down, avoiding the need for frequent manipulation The second difficulty resolves itself with some discomfort to the patient, by the passage of copious watery stools It would seem reasonable, instead of trying to suck the fluid all the way back to the mouth, to let it flow on through a simple duodenal tube and withdraw it by a wide rectal tube Although we had these initial difficulties it was possible to rid the body of 15 g of urea, this amount is much larger than that recorded by Odel and Ferris, using the same principle This may be partly because they employed only a modified Ringer solution, while we followed

Maluf (1948) in using a slightly hypertonic sodium sulphate solution (in our case 4.5 g per 100 ml) The use of the method leads to loss of sodium chloride from the body as well as of urea, and the most convenient way of dealing with this is to carry out dialysis during the day and run in normal saline or Ringer's solution by slow drip through the tube during the night, the amount of saline used depending on the amount found to be lost in the dialysate

Restoration of urine flow, spontaneous or otherwise, is not synchronous with full recovery of renal function, and an apparently satisfactory diuresis may coexist with low values for renal function tests. The patient described here, with post-transfusion anuria, had inulin and "diodrast" clearances of only about half the normal some weeks after urine flow was re-established. Moreover, we have observed inulin-diodone clearance of only a few millilitres per minute in two patients recovering from extreme oliguria following abortion, at a time when both of them were passing large volumes of urine. Patients who have had an episode of anuria should therefore be followed up in much the same way as those who have had an attack of acute nephritis.

Summarizing our present views on the treatment of anuria, we would say that an attempt should be made as early as possible to induce a splanchnic block by medical or surgical means. When this measure fails, as it often will, the patient should be maintained on a diet with about 30 g of protein, a fluid intake limited to one litre a day, and a low salt intake. If spontaneous restoration of urine flow is delayed for more than a few days intestinal dialysis should be carried out in order to lengthen the time available for repair of the damaged kidneys.

### Case Report

A housewife aged 48 was admitted to another hospital for hysterectomy on account of severe menorrhagia and anaemia. On March 30, 1948 she was given a pre-operative blood transfusion of 1 pint (570 ml) of compatible group O packed red cells followed by 1 pint of incompatible stored group A whole blood. She developed lumbar pain and tightness in the chest during the second infusion of blood, and from that time there was virtual anuria. We first saw her on April 2 when the daily output of urine was probably less than 50 ml. The patient appeared well apart from anaemia (60% Haldane) and there was no jaundice (serum bilirubin 0.3 mg per 100 ml). There was a constant slight uterine haemorrhage, making accurate urine collection impossible, but no urine was obtained by catheterization. The blood pressure was 155/100 and the blood urea was 120 mg per 100 ml.

The following measures were carried out in an attempt to establish urine flow. On April 2 she was given 300 mg of tetraethyl ammonium bromide intravenously. This produced a slight fall in blood pressure. On April 3, in an attempt to produce intrarenal vasodilatation (Smith, 1943), a pyrexial reaction was induced by intravenous T A B vaccine (25 million organisms). On the 4th spinal analgesia to D2 produced a small fall in blood pressure but like the other two procedures, failed to induce diuresis. Urine production was still either absent or minimal. The blood urea had risen to 154 mg per 100 ml on April 5 and it was decided to attempt intestinal perfusion. A double lumen intestinal tube without balloon was passed and its entry into the jejunum confirmed by fluoroscopy.

A 4.5% solution of  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$  was led by gravity into the duodenum at the rate of 1 pint in half an hour. Considerable difficulty was experienced in aspirating from the distal end of the tube and vomiting terminated the attempt. Seven pints (4 litres) of solution had been infused and a watery diarrhoea induced, 2,520 ml of watery stools was recovered with a urea content of 150 mg per 100 ml. A total of 378 g of urea was recovered in this way and the urea content of the watery faeces reached 97% of the blood level.

The tube was left in the stomach and slowly advanced the next day, glucose saline solution being administered. On April 7 the ninth day of oliguria, the patient was drowsy and apathetic and the blood urea was 186 mg per 100 ml. Perfusion was restarted and 10 pints (5.7 litres) was infused in about six hours. Aspiration was now more successfully accomplished, but in spite of this a profuse diarrhoea was produced and a not inconsiderable volume of fluid was lost by incontinence. The fluid, urea, and chloride are shown in the accompanying Table. Towards the end of this perfusion the patient

Date	$\text{Na}_2\text{SO}_4$ Infused	Aspirated Dialysate			Watery Faeces		
		Volume (ml)	Cl (as NaCl) mg/100 ml	Urea mg/100 ml	Volume (ml)	Cl (as NaCl) mg/100 ml	Urea mg/100 ml
April 5	7 pints						
7	10 "	5 880	70	34	2 520	140	150
8	3 +	Not collected					

experienced scalding and was aware of passing urine for the first time since admission to hospital (see Chart). The following day she was brighter, and since urine flow was established no further perfusion was carried out although the tube remained indwelling. The blood urea was now 166 mg per 100 ml. Taking into account the steady daily rate at which the blood urea had been rising, a level of approximately 200 mg per 100 ml might have been anticipated. Reckoning a body fluid volume of 50 litres, this represents an extrarenal excretion of approximately 17 g. Actually 147 g of urea was recovered and the deficit might be accounted for by incontinence. On subsequent days the urine volume steadily increased, but it is noteworthy that it was the ninth day after establishment of diuresis before the kidney excreted more than 10 g of urea in

the 24 hours, and even this was at a time when the blood urea level was 238 mg per 100 ml and the urine flow 2,200 ml.

On June 5 four weeks after urine flow was re-established, the inulin clearance was still only 54 ml per minute, and diodone clearance 288 ml per minute giving a filtration fraction of 0.19. At this time the blood urea was only 30 mg per 100 ml and the haemoglobin was 46% (Haldane). This degree of anaemia would account for some

depression of renal function, but simple anaemia of this degree does not lead to such low figures for inulin clearance, and would moreover, be associated with a change in the filtration fraction (Bradley and Bradley 1947). The patient made a good clinical recovery.

### Comment

It will be noted that the total fluid volume recovered after perfusion was greater than that of the sulphate solution introduced. This may indicate that the procedure interferes

with the reabsorption of the water of intestinal secretions. Peritoneal dialysis is often complicated by overhydration, which is one of its many disadvantages. This first experience with hypertonic sulphate dialysis suggests that dehydration and salt loss may be a more likely complication. Since, however, the duodenum is intubated, it is possible, by means of saline or other solution during the night, to make good the losses produced by dialysis during the day.

### Summary

Anuria may be caused by a failure either of the glomeruli to form filtrate or of the tubules to transmit the filtrate in the usual way. Although a circulatory upset would primarily affect the glomeruli the morphological changes in anuria are predominantly tubular, and it is still an open question whether glomerular or tubular functional impairment is the more important. This uncertainty is reflected in the confused opinion about the treatment of anuria. Some methods of treatment (paravertebral block, spinal analgesia) assume a circulatory disturbance to be the cause of anuria, other methods (low-protein diet, the artificial kidney, peritoneal and intestinal lavage) are designed to prolong life until reparative processes can take place in the tubules. At present it seems justifiable to employ suitable methods of the first type as soon as possible, and, if need be to resort to the second type of method as well. A patient is described whose treatment illustrates some of the points discussed in particular the use of intestinal lavage with hypertonic sodium sulphate solution.

We are grateful to Mr H Varley for the estimations on the dialysate and for the clearance results.

### ADDENDUM

Marquis and Schnell (*Amer J med Sci* 1948, 215, 686) report sudden death in a patient after 10 days of intestinal perfusion, the serum potassium just before death was only 1.2 mEq/litre. The danger of death from potassium depletion, once recognized, can easily be avoided by using Ringer's solution rather than normal saline to replace fluid loss overnight.

The American Medical Association sponsored a Public Relations Conference in St Louis recently. The theme was "Common Targets in Medical Public Relations." About 125 State and metropolitan county medical society leaders participated in the public relations meetings. The problems under discussion included 'Selling the Need for Public Relations to the Profession', 'Using Public Relations to Aid Medical Prepayment Plans', 'Handling Emergency and Night Calls', 'The Rebate Problem', 'Co-operating with Special Publics' and 'Co-operating with Health Agencies'.

## SPLENIC ANEURYSM AND SPLENIC ENLARGEMENT IN PREGNANCY

BY

H L SHEEHAN, MD, DSc, FRCP

Professor of Pathology University of Liverpool

AND

NINIAN M FALKINER, MD, ScD, FRCPI  
FRCOG

Late Master, Rotunda Hospital, Dublin

Rupture of an aneurysm of the splenic artery is a well-recognized complication of pregnancy. In a previous paper (Lennie and Sheehan, 1942) four cases of rupture of splenic and renal aneurysms in pregnancy were described and a review was given of 20 previous cases in the literature. More recently Ogden (1948) recorded a ruptured splenic aneurysm in a woman 35 weeks pregnant and gave details from the literature of three additional cases (one splenic and two renal) in pregnant women. The following is a further example of rupture of a splenic aneurysm in the course of pregnancy.

### Case Report

The patient, aged 32, was a 3 para at 36 weeks' gestation. One day, at 1 p.m., she had a sudden onset of abdominal pain, felt faint, and went to bed. Foetal movements ceased at this time. She vomited in the evening and was sent into the Rotunda Hospital with the diagnosis of concealed accidental haemorrhage. There was no vaginal haemorrhage or albuminuria, but foetal heart sounds could not be heard and the abdomen was resistant and slightly tender. Her general condition was poor: pulse 80, B.P. 105/80. At 6 a.m. next day she suddenly developed severe shock, which was treated with saline and blood transfusion. The os was dilated two finger breadths so the membranes were punctured and "pitocin" was given, the liquor amni was not blood-stained. Labour did not begin but at 8 a.m. she suddenly became very collapsed and a further blood transfusion was necessary. Soon afterwards a classical section was carried out, this showed no uterine haemorrhage, but a large retroperitoneal haemorrhage in the region of the pancreas and left kidney was found. This was diagnosed as a ruptured aneurysm of the splenic or renal artery, but the patient was considered to be too ill for a surgical exploration of these vessels. At 10 p.m. the patient suddenly collapsed again and in a few minutes she died. The time from the first symptoms to death was thus 33 hours. Post-mortem examination showed a rupture of a small aneurysm of the splenic artery: the blood had finally burst through into the peritoneal cavity.

### Discussion

The case is fairly typical—the diagnosis of some intra-abdominal catastrophe, the operative discovery of the haematoma in the region of the pancreas, the latent period (which varies in different cases between one and seven days), and the terminal haemorrhage into the peritoneal cavity. The only hope for such a patient is heroic surgery by the operator who has opened the abdomen, usually the obstetrician who has performed caesarean section. The details have been discussed by Lennie and Sheehan (1942).

The aetiology of these aneurysms is not known. One peculiar aspect of the problem is that, of the cases so far recorded in patients below the age of 45, splenic aneurysms are much commoner in women (41 female, 12 male), whereas renal aneurysms are commoner in men (9 female, 21 male). What is of more direct interest here, 23 of the splenic aneurysms ruptured in connexion with pregnancy, nearly always at seven to nine months' gestation. This raises the question whether the rupture may possibly be related in any way to alterations of the blood supply to the spleen during pregnancy. No direct evidence is available on this subject, but some facts which may have a

possible bearing on it have been obtained from observations on the spleen in an unselected series of 163 routine obstetric necropsies. In the course of this work it became obvious that there was some relation between splenic enlargement and gross hyperplasia of bone marrow, so the details about the latter are included in this analysis.

In the normal adult the spleen has a mean weight of 150 g, with a range of from 80 to 200 g. The observations made by Turnbull (Vaughan, 1936) on the bone marrow in normal non-pregnant patients may be briefly summarized here. His data were obtained, as in the present cases, from longitudinal section of the whole length of the femur. He found that between the ages of 15 and 20 the marrow is fully red with specific gravity over 1000,

Chart showing weight of spleen and length of red marrow in femur in obstetric necropsies. ● = Severe anaemia of pregnancy, accidental haemorrhage, or uterine sepsis and thrombophlebitis. ○ = Other clinical conditions. The panel in the left lower corner encloses the normal range in non-pregnant adults.

but in the other 40% it has a weight range of from 200 to 550 g, so that the mean weight over the whole series is 200 g. The red bone marrow of the femur is usually hyperplastic, though it varies from only a slight amount at the head of the bone to a complete replacement of all the yellow marrow down to the condyles. The age of the patient is without influence on the marrow hyperplasia. On the average the upper 16 cm is fully red marrow with a specific gravity of over 1000, and the next 6 cm is partly red marrow with a specific gravity below 1000. For convenience the amount of red marrow is represented in this paper by a single figure—the length of the fully red marrow plus half the length of the partly red marrow.

The relation between the size of the spleen and the amount of bone marrow in the present series of obstetric necropsies is shown in the above Chart. Apart from the conditions specifically mentioned below, there were no diseases of the type which give rise to enlargement of the spleen and bone marrow in ordinary pathology—e.g., leukaemias, Bant's disease, tropical diseases, etc. The individual cases have been analysed in a search for significant factors. This analysis shows that in obstetric patients the following three clinical conditions are commonly associated with enlargement of the spleen and red marrow.

**1 Severe Anaemia of Pregnancy.**—In 9 cases the mean weight of the spleen was 360 g and the mean length of the red marrow of the femur was 29 cm. It is possible that some of the other patients with enlargement of the spleen and red marrow were anaemic but were not noted as such in the clinical records; many of them were obstetric emergencies and had not been examined haematologically.

**2 Accidental Haemorrhage of Abruptio Type.**—In 10 cases the mean weight of the spleen was 275 g and the mean length

of the marrow 23 cm. Eclampsia and the other toxæmias of pregnancy and shock or haemorrhage did not appear to be associated with these pathological increases.

**3 Puerperal Thrombophlebitis or Gross Septic Endometritis.**—In 15 cases the mean weight of the spleen was 290 g and the mean length of the marrow 18 cm. On the other hand, general peritonitis, empyema, pneumonia, pyelonephritis and chronic valvular disease of the heart were not associated with enlargement of the spleen or marrow.

In the Chart these three clinical conditions are differentiated from the others. It will be seen that they account for most of the large spleens and red marrows, though they do not invariably cause such enlargement. Most of the small spleens in this group were in cases of septic endometritis without thrombophlebitis.

Two other findings from the analysis may be mentioned: (a) the pathological changes were not related to the age or parity of the patients, nor to whether the patient was still pregnant or had been delivered, and (b) there was some association between the enlargement of the spleen and the duration of pregnancy. The higher figures in the

Gestation	No. of Cases	Mean Size	
		Spleen	Marrow
0-20 weeks	16	145 g	16.0 cm
21-30	10	175 g	18.5 cm
31 weeks to term	137	203 g	19.0 cm

cases after the thirtieth week of gestation are partly due to the inclusion in this group of most of the patients suffering from the three significant clinical complications. It is, however, worthy of note that the largest spleen in the patients before the twentieth week of gestation weighed only 190 g.

The essential point that emerges from this analysis is that during the course of pregnancy a number of patients have considerable splenic enlargement, which develops in the second half of gestation and is usually associated either with anaemia or with accidental haemorrhage. This is presumably accompanied by some alteration of the blood supply to the spleen. There is as yet insufficient information to indicate whether or not this is related to the relatively high incidence of rupture of splenic aneurysms in late pregnancy, but this aspect should be considered in future cases of such aneurysms.

## CALCIFIED CYST OF SPLEEN

BY

JOHN H. DONOVAN, F.R.C.S.D.

Honorary Surgeon Camborne and Redruth Hospital

The following seems to be the seventh recorded case of calcified splenic cyst, and the second reported in this country. There is little to be found about cysts of the spleen in the textbooks. The literature of the condition was reviewed by Harmer and Chalmers (1946), and at that date 163 cases of splenic cysts of all types had been recorded. Different classifications of the types of cyst have been made, that of Fowler (1940) being the most comprehensive. For practical purposes it would seem sufficient to classify them as parasitic, true, and false. Hydatid disease accounts for approximately 2% of recorded cases. True cysts are of endothelial origin and are usually multiple—numerous daughter cysts surrounding a large mother cyst. Congenital

polycystic spleen is occasionally found post mortem. The solitary false cyst is probably the end-result of a haematoma.

### Case Report

A spinster aged 50 complained of vague abdominal pain and intermittent attacks of nausea and vomiting. During routine barium meal examination a shadow was seen, no other abnormality was found. Of the possible diagnoses, calcified hydatid cyst of the liver was thought to be the most probable. Casoni's reaction was negative and the blood investigations were normal. The diagnosis of calcified aneurysm of the splenic artery, of which 90 cases are on record, was discounted because of the absence of bruit. The spleen was not palpable in the other recorded cases; the palpability of the spleen was stressed as a diagnostic factor.

By transthoracic approach a portion of the left ninth rib was removed under closed-circuit cyclopropane anaesthesia and the lung partially collapsed. The cyst could then be seen pressing the diaphragm upwards. On opening the diaphragm over the bulge the cyst was found to occupy the greater portion

time of writing has not been confirmed by operation. In the discussion on his case the point is made that trauma may play a part in the aetiology. If there is a preceding prothrombin deficiency, trauma may well be a precipitating factor. No history of trauma could be elicited in my case.

### Summary

A case of calcified cyst of the spleen is recorded.

Calcified shadows discovered by the radiologist in the left upper quadrant of the abdomen may be hydatid disease of the liver or spleen, calcified haematoma of spleen, or calcified aneurysm of the splenic artery, of which 90 cases are recorded and which are accompanied by bruit. Calcified tuberculoma of the spleen may occur.

Cysts of the spleen are not necessarily palpable.

## Medical Memoranda

### A Case of Dracontiasis

The following case of infestation with *Dracunculus medinensis* is considered worthy of record on account of the highly unusual pathological features.

#### CASE REPORT

An adult male African aged 26 was admitted to hospital on Nov. 1, 1944, with a diagnosis of left indirect inguinal hernia. He stated that he had had a lump in his groin for four years. He had never had any pain or discomfort.

On examination he was found to have a small indirect left inguinal hernia, which was easily reducible and which did not extend into the scrotum. No other abnormality was discovered. Blood films were negative for both malaria parasites and microfilariae. A differential white cell count showed an eosinophilia of 8%.

Operation was performed on Nov. 4 through a left inguinal incision. When the hernial sac was isolated its wall was seen to be grossly thickened and fibrosed. On opening the sac it was found to contain part of a female guinea-worm. The head and about 2 in. (5 cm.) of the body of the worm were lying free in the lumen, the remainder being embedded in the wall of the sac on the antero-lateral aspect. The head of the worm was gently grasped in a haemostat, and by twisting the instrument slowly steady traction was maintained on the worm, which was drawn out intact. The operation was concluded in the normal manner, convalescence was uneventful, and the wound healed by first intention. The sutures were removed on the seventh day and the patient was discharged on the 21st day.

**Pathology.**—Although the worm closely resembled *Dracunculus medinensis* on superficial examination, the unusual site of infestation led to some doubt about the diagnosis. The worm was therefore carefully examined in order to make certain of the species. The overall length was 23.7 cm. and the mean diameter 1.4 mm. The body was an elongated cylindrical cord with a rounder anterior end and a hooked posterior end. The mouth parts and genitals were typical of *Dracunculus medinensis*. No male was found, and the worm did not appear to be gravid.

#### COMMENT

Although rather smaller than usual, the worm, as described, conformed in all other ways to the characteristics of the species *Dracunculus medinensis*.

Stitt (1943) states that in 1% of cases of dracontiasis the site of infestation is the scrotum. There seems to be, however, no previous record of the worm occurring in a hernial sac.

I am indebted to the Director of Medical Services, Nigeria, for permission to publish this case.

W. L. M. PERRA, M.D.

#### REFERENCE

- Stitt, E. R. (1943) *Diagnosis and Treatment of Tropical Diseases*, 6th ed. p. 1388.

of an otherwise normal spleen (see Fig.). There were numerous adhesions, especially to the stomach, and it is assumed that these were the cause of the symptoms. Splenectomy was performed and the wound closed. Convalescence was uneventful and the patient left hospital two weeks after operation.

### Discussion

In the case recorded by Snoke (1943) the patient had been examined a few months previously for subacute cholecystitis, and no calcified shadow had then been visible on the radiographs. When the calcified cyst was removed and investigated no lining membrane was found, and Snoke considered it to be a calcified haematoma. The cholecystogram had revealed impaired liver function, and the haematoma probably resulted from the consequent hypoprothrombinaemia. Since calcification has been demonstrated in haematomata within twelve days of their appearance this seems a very reasonable hypothesis. In my case no lining was found, the cyst contained a few drachms of serum. It is interesting to note that two weeks after the patient left hospital she had a transient attack of jaundice, and therefore probably an associated hypoprothrombinaemia. I consider that this also was a calcified haematoma. Bazeley (1948) presents a similar case for diagnosis, which at the

### RHEUMATIC DISEASES

*Textbook of the Rheumatic Diseases* Edited by W S C Copeman OBE, MD, FRCP Compiled by 24 contributors (Pp 612 351 illustrations some in full colour £2 10s) Edinburgh E and S Livingstone 1948

A good textbook should reward the reader with understanding, not merely with information. This attribute demands a very carefully planned structure, a perfect architecture. Dr Copeman has edited what is intended to be a textbook for those young medical men who have decided to embark on a specialist career in the rheumatic diseases. But if you ask twenty-four men to write a book it is exceedingly difficult to give it any structure at all—a good integration of the teaching they have to offer would involve co-operation in the making of each chapter. In this case the result is not a textbook but a symposium, with the inevitable repetitions and sense of discontinuity. It is, however, a very good book of its kind. A volume of thirty chapters, it is superbly produced, profusely and well illustrated.

Among the outstanding contributions is Professor Henry Cohen's chapter on gout, probably the best general account in modern writings. M J Gibson, in his chapter on clinical pathology, agrees with him that the estimation of blood uric acid should be carried out on plasma or serum and not on whole blood and states that plasma uric acid is higher than whole blood uric acid by 1.0 to 2.0 mg, making the upper limit of normal 6 mg per 100 ml. This figure should not be accepted without confirmation. We have reason to believe that it will not be confirmed for we have found no difference greater than 0.25 mg, and sometimes identical figures, if it is inaccurate it may lead to serious diagnostic errors. Professor Cohen agrees with the old statement that in gout "the roentgen ray is of very little service from a diagnostic standpoint." Dr Campbell Golding in a most helpful chapter on radiology, shows how the diagnosis may often be established by an examination of both hands even in the absence of local clinical signs.

Mr H J Kellgren contributes two chapters summarizing and discussing the significance of his experimental work on somatic pain. They would perhaps be more appropriately placed immediately before the editor's chapter on non-articular rheumatism. Dr Copeman discusses several hypotheses on the nature of those "trigger points" from which the pain of fibrositis is referred segmentally including his own recent addition to our knowledge of oedema and tension in fat lobules and herniation of a bit of fat through its fibrous covering. The student may get the impression that what is merely hypothetical in this chapter—and there is much of it—is well verified theory. He is told for example, that he should inject a "trigger point" with a comparatively large volume of novocain solution, driving the fluid forcibly into its substance to disrupt it—a procedure grounded on a speculative proposition.

Dr M J McArdle contributes a chapter on brachial neuralgia. The reader may ask what descriptions of cervical disk lesions, cervical rib and allied pressure syndromes, acroparaesthesia, pachymeningitis, causalgia, and other neurological disorders are doing in a book on rheumatism. They are not rheumatic diseases by any definition of this muddle-headed name but are properly included for their importance in differential diagnosis. But tuberculous arthritis is at times quite alarmingly important in diagnosis, and yet its clinical description is confined to one entirely inadequate paragraph.

Sr Reginald Watson Jones and Mr H Osmond Clarke contribute two chapters on the orthopaedic treatment of arthritis. 'The day has passed' they say 'when patients with generalized arthritis were distributed fortuitously between orthopaedic surgeons who sometimes failed to recognize metabolic or biochemical aspects of the problem and physicians who sometimes failed to preserve joint function or prevent deformity. Has it?' Not until the physicians have absorbed the relevant orthopaedic principles so ably expounded in these excellent chapters and their surgical orthopaedic colleagues have become

aware that there is a science of orthopaedic medicine can we hope for more rational distribution or timely co-operation.

KENNETH STONE

### ENDOCRINE DISORDERS

*Major Endocrine Disorders* By S Leonard Simpson, MA MD, FRCP Second edition (Pp 552 89 figures £2 2s) Oxford Medical Publications London Geoffrey Cumberlege (Oxford University Press) 1948

The second edition of this well-known work appears ten years after the first. Not only has the author brought it thoroughly up to date, but he has further improved it by giving a list of references at the end of each section. The result is a work which combines in good balance the extensive personal experience of the author in clinical endocrinology with a critical appreciation of the relevant literature. The references are well chosen and are designed to enable the student to pursue the subject further for himself.

The author introduces many of his own ideas, and discusses, for instance, such clinical conditions as diabetes, tenuifacies, and adipose gynandrium, which have been described by him. He rightly points out that failure of sexual maturation should be an essential feature of true Frohlich's syndrome, but that the majority of cases of the Frohlich type do eventually achieve some degree of sexual maturity. It is to these that he gives the name adipose gynandrium.

The style of the book is throughout stimulating and thought provoking. In the chapter on adrenal hypercorticalism the author states as his aim 'to attempt a rationalization of existing knowledge aiming at lucidity undivorced from factual evidence, and indicating discrepancies where such exist'. He has achieved his aim well, not only in the chapter on hypercorticalism, in the development of knowledge of which the author has played such a prominent part, but also in many other sections of the book. The sections on eunuchoidism, castration, and sexual disorders are also well written, presenting as they do the results of the author's own wide experiences in these fields. He refers to the treatment of hyperthyroidism with radioactive iodine, having seen excellent results with this method.

In the chapter on obesity he does not mention the recent vogue for the use of amphetamine to control appetite, and we are left in doubt of his views on the subject. All references relating to diseases of the thyroid are grouped together, since some of the authors listed are not directly referred to in the text, the subject matter of some of the papers quoted cannot be determined from the text. But these are minor points of criticism. The book is well illustrated and well produced and may be thoroughly recommended to students, general practitioners, and consultants.

### DEMAND ON UNIVERSITIES

*The Problem Facing British Universities* Nuffield College (Pp 131 5s) London Geoffrey Cumberlege (Oxford University Press) 1948

The problem is how to cope with the increased demand for university education. Some of the demand is unreal. A university degree is no more necessary for sick-nursing than for breast-nursing and the committee therefore makes no allowance for student nurses in the calculation of future numbers in medical schools. It estimates the real demand as an increase of intake into the universities from 14,200 to 22,200 a year, and an increase in the total undergraduate population from 50,590 to 80,000. There are two main sources of demand. The first is the need for more scientists of all kinds in particular scientists for industry and more science teachers in the secondary schools. The second is the raising of the age for leaving school, the increased number of children taking the Higher Certificate examination and the growing subsidy of university education by the Government and the local authorities. Up to the present the solution of the problem has been postponed by overwork, overcrowding, and some lowering of standards in the universities. There were nearly 77,000 university students in the autumn term of 1947. What is to be done in the future?

Post-war planning has hitherto been vitiated by two major errors. The one is the fallacy of 'the bigger, the better'. Any

scientist knows that you cannot enlarge a flea to the size of an elephant and still expect it to jump or put a plank bridge across Niagara, but the social planners still seem to have to learn this natural law by painful experience. The other fallacy is what has been called "the blue print without the engine," in other words, the disregard of incentives. The Vice-Chancellor of Oxford in his Annual Oration this year pointed out that the two major problems facing the university to day are: What is to be its size? and, How is a proper balance of studies within it to be maintained? Our universities have already reached, if they have not passed the limits of effective size for a community within which all the arts and faculties are taught and studied and there is free exchange of ideas. Administration takes up so much time that the last thing a man who loves learning and the pursuit of knowledge now wishes to be is the head of a university department.

The Nuffield College Committee states the problem and barely hints at a solution. It seems clear that there must be a more ruthless separation of university and technical education and the creation of more technical colleges. The distinction between university and technical education is fully discussed in Aldous Huxley's *Ends and Means* so I need not go into it here. It is more urgent to think of the future of the medical schools. They are being affected by three tendencies which were overlooked in the Goodenough and B.M.A. curriculum reports. The first is the pressure on the universities to extrude technical forms of education. The second is the increasing preoccupation of the clinical schools with regional medical planning and administration. The third is the widening of the rift between clinical and non clinical teachers by the Spens Reports. The effect of these tendencies may well be to bring about a complete break between preclinical and clinical education. In other words the Oxford and Cambridge practice of a preclinical education within the university and a clinical education in separate and autonomous teaching hospitals may become the pattern for medical education throughout Britain in the future.

L J WITTS

### TEXTBOOK FOR ALMONERS

*Textbook for Almoners* By Dorothy Manchec, Almoner, St Mary's Hospital, with foreword by Sir Alfred B. Howitt, CVO, MD (Pp 466, 7 plates 49 figures £1 7s 6d) London: Baillière Tindall and Cox 1947

This is the first textbook written for hospital almoners. It lacks encyclopaedic accuracy but it is written in a pleasant style. The account of the first 50 years of the profession is interesting. The first almoner was appointed in 1895 at the Royal Free Hospital. It was Sir Charles Loch, of the Charity Organization Society, who had seen the need for the almoner, a man or woman of some insight, prompt decision, and firmness 'to supplement the work of the medical man by obtaining the general assistance without which medical relief would often fail in its purpose.'

After a slow start the number of almoners appointed to hospitals increased rapidly during the decade 1915-25, but the reasons behind the new interest in almoning were regrettable. Many almoners were appointed only to assess the patient's ability to pay. It is true that the newly appointed almoners eagerly seized the opportunity to do invaluable social work for the patient's but a misconception grew up in the public mind that the almoner was a tax gatherer. Now the almoner can look forward to a new phase in her career when the National Health Service Act banishes the uncongenial duties of assessment and leaves her with increased time and opportunity for her real work. The general practitioner can hope that eventually he too will have her invaluable consultant assistance with the growth of health centre practice.

For the rest the author is unfortunate in her times, which make so much of the detailed information she provides on social agencies already out of date. There is altogether too much about London in a book intended for almoners everywhere. The value of the sketchy and sometimes inaccurate accounts of clinical details is questionable. It would have been interesting to have seen more discussion of the social background of disease in a book for almoners. But the author deserves the credit which goes to the pioneer.

J H F BROTHERSTON

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Twelve Years with Roosevelt* By Vice-Admiral Ross T. McInure (Pp 244 12s 6d) London: Putnam 1948

The author was physician at the White House and a personal friend of President Roosevelt.

*Osteo Arthritis of the Hip-Joint* By H. Warren Crowe D.M., B.Ch., M.R.C.S., L.R.C.P. (Pp 70 No price) London: George Pulman and Sons 1948

A monograph on treatment based on the author's experience.

*History of Factory and Mine Hygiene* By L. Teleky M.D. (Pp 342 25s) London: Geoffrey Cumberlege 1948

The author discusses the prevention of occupational illness from antiquity to the present day.

*A Penicillin per Via Arterialis ad Osteomyelites* By E. B. Ribeiro (Pp 124 No price) Brazil: São Paulo 1947

A monograph on the treatment of osteomyelitis with intra arterial penicillin.

*New Fields of Psychiatry* By D. M. Levy, M.D. (Pp 171 12s 6d) London: Chapman and Hall 1948

An account of psychiatry in child guidance, delinquency, education, industry, and other spheres outside the hospital.

*Handbook of Orthopaedic Surgery* By A. R. Shands Jr. B.A. M.D., and R. B. Raney, B.A., M.D. 3rd ed. (Pp 574 \$6.00) St. Louis: C. V. Mosby 1948

A manual for the student and general practitioner.

*A Textbook of Histology* By A. A. Maximow and W. Bloom 5th ed. (Pp 700 42s) London: W. B. Saunders 1948

The authors present the subject from a functional point of view.

*General Cytology* By E. D. P. De Robertis, M.D., and others (Pp 345 27s 6d) London: W. B. Saunders 1948

A review of modern cytology translated from the Spanish.

*Black's Medical Dictionary* By J. D. Comrie, M.D., F.R.C.P. Ed., revised by W. A. R. Thomson, M.D. 19th ed. (Pp 995 25s) London: Adam and Charles Black 1948

The material has been revised and some new plates included.

*The Skin Diseases* By J. Marshall, M.D., B.S., M.R.C.S., L.R.C.P. (Pp 363 30s) London: Macmillan 1948

A manual for students and general practitioners.

*Preoperative and Postoperative Care of Surgical Patients* By H. C. Ilgenfritz, A.B., M.D., F.A.C.S. (Pp 898 \$10.00) St. Louis: C. V. Mosby 1948

The author gives the physiological basis for his recommendations as well as detailed instructions.

*Rh Factor Selected Reprints* By A. S. Wiener A.B., M.D., F.A.C.P. (No price) Brooklyn: New York 1948

Bound reprints of the author's papers on the Rh factor intended chiefly for libraries.

*The Epithelia of Woman's Reproductive Organs* By G. N. Papanicolaou, M.D., and others (Pp 53 55s) London: Geoffrey Cumberlege 1948

The author emphasizes the relation between cytological changes and the phases of the menstrual cycle.

*Investigations on Agonal Acidosis* By I. F. Hansen (Pp 134 No price) Copenhagen: Povel Branner 1948

The study is based particularly on electrolyte determinations on blood collected just before or after death.

*An Introduction to Surgery* By R. Morison, M.D., F.R.C.S., F.R.C.S. Ed., M.A., D.C.L., LL.D., and C. F. M. Saint CBE, M.D., M.S., F.R.C.S., F.R.A.C.S. 4th ed. (Pp 330 42s) London: Simpkin Marshall 1948

A guide to make the student think for himself about problems he encounters in the wards.

SATURDAY DECEMBER 25 1948

## CONTROL OF GASTRIC SECRETION

The stomach is a much more complicated organ than is generally supposed. The mucous membrane of the fundus and body contains the main gastric glands composed of chief cells and oxyntic cells which secrete pepsin and hydrochloric acid respectively, the distal or pyloric part contains glands which secrete mucus and alkali, and the surface epithelium secretes mucus only. The intrinsic factor has been demonstrated in the region where the main gastric glands are found, and it is well established that lesions of the proximal part of the stomach may give rise to pernicious anaemia. By a time-honoured convention the term gastric juice is applied to the acid-pepsin mixture which is secreted by the proximal part of the stomach, but the juice secreted by the stomach as a whole is also rich in mucus, and its reaction depends largely on the relative amounts of acid and alkali secreted by the proximal and distal parts. It has also been proved that the stomach releases into the portal circulation a hormone, gastrin, the structure of which has not yet been identified. The control of gastric secretory activity is both nervous and chemical. The vagi are the secretory nerves which are stimulated reflexly from receptors of taste, sight, and smell to produce the appetite or psychic juice which is rich in acid, pepsin, and mucus. Vagal activity is also accompanied by marked vasodilatation. It is not yet known whether the vascular changes are due to specific dilator fibres in the vagi or whether they are secondary to the release of dilator metabolites as a result of gastric activity.

The influence of emotion on the activity of the stomach is now generally recognized, especially since Wolf and Wolff<sup>1</sup> published the results of their studies. Fear leads to sympathetic overaction: the gastric mucosa becomes blanched and its secretory activity is depressed. States of anxiety and resentment lead to vagal overaction, with excessive secretion of acid, pepsin, and mucus and intense congestion and swelling of the mucous membrane, in extreme cases haemorrhage and destructive changes in the mucosa may occur. It is reasonable to suppose that such gastric reactions may precede the development of gastric ulcers and prevent their healing, the surgeons have put this hypothesis to the experimental test and are studying the effects of double vagotomy on gastric ulcers. The immediate results, though encouraging, are as yet inconclusive: so many cures of gastric ulcer have come and gone that a final decision on the value of this new operation must await the follow-up of the cases over a long period. The physician too has something to learn from these observations—namely, that the treatment of gastric ulcer should be directed to the mind no less than to the stomach. The disease is an outstanding challenge to the advocates of the importance of psychosomatic relationships.

The chemical phase of gastric secretion has been the subject of so much controversy that Professor Georg Kahlson's authoritative review of the subject in this issue is particularly welcome. Pavlov<sup>2</sup> demonstrated that after cutting the vagi and sympathetic nerves and thus severing all the connexions between the stomach and the central nervous system the introduction of certain foodstuffs into the stomach or intestine called forth a further flow of gastric juice rich in acid but poor in pepsin. The most potent excitants are meat extracts and certain products of food digestion, but the full list of effective agents is a long one and includes acids, alkalis, salt, alcohol, saliva, pancreatic juice, and bile. These substances do not act by being themselves absorbed into the circulation, since they have no secretagogue action when they are injected intravenously, and there is convincing evidence that they release the hormone now called gastrin into the blood. Mechanical stimulation of the pyloric region also releases gastrin, this result may explain why gastric distension is commonly associated with increased gastric secretory activity. The experimental evidence indicates that gastrin is released mainly but not exclusively from the pyloric region, it is also formed in the adjacent region of the body of the stomach (the "intermediate zone"), the duodenum, and perhaps over a wider area.

The chemical identity of gastrin has now been satisfactorily established, thanks to researches carried out in the laboratories of Kahlson and Babkin.<sup>3,4</sup> Both groups of workers agree that gastrin is a protein of low molecular weight closely resembling secretin in its chemical properties. Relatively crude gastrin preparations stimulate the stomach to secrete a juice which is rich in acid and poor in, or even devoid of, pepsin, they also have some action on the pancreas and liver. More carefully purified preparations act only on the stomach and on no other glands, they have no effect on the circulation. These results finally dispose of Ivy's original suggestion that gastrin is identical with histamine. This view was put forward on the grounds that gastric extracts are rich in histamine and that histamine stimulated gastric secretion. It always seemed unlikely from teleological considerations that the gastric hormone should be a substance, like histamine, which had a widespread secretagogue action (promoting, for example, a flow of saliva and tears) and which also produced generalized vasodilatation and other undesirable circulatory effects. The specific action on the stomach of the newly isolated gastrin and the absence of side effects seem to fit the substance well to carry out its function as a secretagogue hormone released during gastric digestion and reinforcing the initial flow of vagus juice.

It is doubtful whether gastrin fully accounts for the chemical phase of secretion. As Pavlov showed, the introduction of an excitant into the stomach produces a flow of juice which contains less pepsin than vagus juice but more pepsin than is found in the juice secreted after the injection of gastrin. This discrepancy suggests the possibility that a second hormone may be liberated which acts on the peptic cells and not on the oxyntic cells to which gastrin confines its action. Kahlson now reports that crude pyloric extracts have been prepared which in fact do increase the secretion of pepsin, if this work is

confirmed and a name is needed for the new substance, then the term gastrozimin might not be inappropriate, since it would bring the terminology for the gastric hormones in line with that of the hormones controlling pancreatic secretion. It will be recalled that Bayliss and Starling first isolated from the intestine the substance secretin, which stimulates the pancreas to secrete an alkaline enzyme-free fluid, while quite recently Harper and Raper<sup>5</sup> have isolated a second hormone from the intestine which they have named pancreozymin, which stimulates the secretion of the pancreatic enzymes. There are thus very close resemblances between the mechanisms which control the secretion of gastric juice and pancreatic juice.

Although it is now known that gastrin is not histamine, the latter still remains a substance of great interest in relation to gastric function. When injected in man it specifically stimulates the oxyntic cells of the stomach to secrete a profuse, highly acid secretion which is poor in enzyme content. The absence of this acid response to repeated injections of histamine indicates temporary dysfunction, atrophy, or destruction of the oxyntic cells. Histamine may, however, also play a part in the normal control of gastric secretion. It has been proved that the post-ganglionic fibres of the vagi, like all parasympathetic post-ganglionic fibres, release acetylcholine at their terminals. There is now good reason to suppose that, though the acetylcholine acts directly on the peptic cells, it acts indirectly on the oxyntic cells through a second intermediary which is probably histamine. Kahlson discusses the evidence for this suggestion and draws attention to some significant observations such as the high histamine content of gastric extracts and the absence of the histamine-destroying enzyme (histaminase) from the gastric mucosa. Though there is still a conflict of testimony, some workers<sup>6</sup> claim to have demonstrated the presence of histamine in the gastric juice in higher concentrations than are found in the plasma, whether the secretion was stimulated by the vagus or by the presence of food in the stomach. Support to this view is given by the recent demonstration<sup>7</sup> that the injection of a purified preparation of histaminase annuls the secretion of acid normally produced by food or by the parasympathomimetic drug mecholyl, but it is as yet uncertain whether histaminase was the gastric depressant agent in the preparation used, though that seems the probable explanation. The secretion of gastric juice in response to nervous or chemical stimuli is inhibited by enterogastrone, which is released when fat comes in contact with the mucosa of the duodenum and stomach.

Professor Kahlson reviews the findings of Uvnas,<sup>8</sup> which suggest that gastrin (or some associated pyloric hormone) is linked up with the gastric vagal secretory mechanism in a number of ways. The vagus fibres which supply the pylorus (and regulate the secretion of alkali and mucin by the mucosa) may stimulate the release of gastrin into the blood, the unidentified gastrin-forming tissue is thus supposed to be activated by nervous as well as by chemical

influences (various foodstuffs and products of digestion) and by mechanical stimuli. This would not be an unusual arrangement, for other endocrine tissues are controlled predominantly by chemical and to a minor extent by nervous influences, the islets of Langerhans and the thyroid are examples. Uvnas claims further that the role of gastrin is not merely to stimulate the oxyntic cells directly to secrete acid, he believes that gastrin must be present if the vagus is to exert its secretory action on the main gastric glands. Thus he finds that, if the pylorus is excised, deprived of its blood supply, or poisoned with cocaine, stimulation of the vagi in the fasting animal fails to elicit the usual profuse flow of an acid- and pepsin-rich juice from the main gastric glands, though these are directly innervated by the vagi, but if gastrin is infused into these animals (in concentrations which in themselves are ineffective) concurrently with vagal stimulation, the normal response characteristic of the intact animal is obtained. Uvnas thus argues that gastrin is an indispensable part of the transmission mechanism at the vagal terminals in the stomach. His conclusions, if confirmed, would open a novel field of inquiry of great theoretical interest, and they would have their practical implications too. The operation of pylorotomy, by removing much of the gastrin-producing mucosa, might be supposed not only to decrease the chemical stimuli to gastric secretion but also to depress the efficacy of the nervous mechanisms. Similarly the operation of vagotomy, in addition to abolishing the nervous control, might also be expected to depress the chemical stimuli to the stomach. The fact that opinions are still so divided about the most appropriate surgical treatment for gastric ulcer suggests among other conclusions that the secretory control of the stomach, being multiple, can continue to function at a moderate level even if some of the secretagogue agencies are put out of action. A more detailed study of the response to insulin, which stimulates the vagal secretory fibres to the stomach in patients subjected to pylorotomy, might help to solve the questions raised in this discussion.

## TREATMENT OF ANURIA

The term "low nephron nephrosis" was used by Lucke<sup>1</sup> to describe the renal lesions produced by a wide variety of conditions which may be associated with shock. In this issue of the *Journal* Drs D A K Black and S W Stanbury discuss the pathogenesis and treatment of anuria with special emphasis on anuria caused by the lower nephron nephroses. Shock is probably not a necessary precursor, for a similar clinical picture may be found in its absence. The lesions of lower nephron nephrosis are found in the crush syndrome, after intravascular haemolysis, abortion, various poisonings, and in many other states. Microscopically the condition is characterized by widespread tubular damage. There has been much discussion about its pathogenesis, and two rival hypotheses have been put forward to explain it. The one school, headed by Trueta and Barclay and their colleagues,<sup>2</sup> believes that the primary disturbance is a rearrangement of the circulation in the kidney, blood from the cortical nephrons being shunted to the relatively scanty

<sup>8</sup> *Acta physiol scand* 1942, 4 Suppl XIII

juxtamedullary nephrons. According to Trueta these inner nephrons are less efficient in filtering the plasma than the cortical ones, with the result that there is a very considerable diminution of glomerular filtration, and anuria or extreme oliguria results. By injecting glass beads of various sizes into the renal artery and recovering them from the renal vein Simkin and his colleagues<sup>3</sup> have produced evidence of arterio-venous anastomoses in the normal kidney of up to 440  $\mu$  in diameter. These anastomoses are not the same as the shunt described by Trueta, and their discovery further widens the field of speculation about the importance of vascular rearrangements in causing this condition. The other school of thought postulates that the tubules are at fault: either these are blocked, or the filtrate is reabsorbed almost completely through the damaged epithelial membrane or through tubulo-venous anastomoses.<sup>1,6</sup>

Black and Stanbury discuss the relative merits of these two views and conclude that it is probable that both vascular and tubular factors are responsible for the anuria. Treatment, they consider, should have three main purposes. First, efforts should be made to restore normal renal circulation. The Trueta shunt can be prevented by cutting or blocking the sympathetic nerve supply to the kidney. With this end in view splanchnic block or spinal anaesthesia may be carried out, or sympatholytic drugs such as tetraethylammonium bromide or dibenamine can be used. Black and Stanbury rightly point out that it is "never possible to exclude an opportune spontaneous recovery of urine flow." Experimental proof of the part played by the Trueta shunt in the lower nephron nephroses and proof of the efficacy of this type of treatment are still lacking, but should be possible to obtain. In the meantime there appears to be little danger in such measures provided that the patient's peripheral circulation is adequate.

The second purpose of treatment is to maintain a normal internal environment by regulation of the intake of potentially toxic substances. It seems likely that the end-products of protein breakdown other than urea are toxic, and protein metabolism should therefore be kept at the lowest possible levels. Because of the protein-sparing effect of carbohydrate Black and Stanbury recommend a diet of 2,500 calories, made up mostly of fat and carbohydrate but with 30 g of protein. This amount of protein contains approximately 5 g of nitrogen. In principle they follow Borst,<sup>7</sup> who gives a high calorie diet almost completely free of protein, but they consider Borst's diet so unpalatable as to be impracticable. There is no evidence that a diet containing 5 g of nitrogen spares the body's nitrogen stores

and is as effective as Borst's regime, and it might be argued that this amount of nitrogen allows protein breakdown to go on at approximately twice the desirable absolute minimum rate.<sup>8</sup> It is generally agreed<sup>9,12</sup> that an excessive fluid intake is dangerous in anuria, and Black and Stanbury recommend restriction of fluid intake to approximately 1 litre per day. They point out that the body has no effective path for electrolyte loss other than from the kidneys and accordingly recommend a salt-free diet during the period of anuria. It is also important that the diet should be as nearly as possible free of potassium. In anuria the level of potassium in the blood may rise to dangerous heights and cause death.<sup>13</sup> Common sources of potassium which should be avoided are potassium citrate given as a diuretic and bottled fruit drinks.

The third purpose of treatment is to maintain a normal internal environment by the removal of toxic substances through extrarenal routes. There are a number of dialysis methods which effectively remove toxic substances from the body. After consideration of some of the difficulties in the use of peritoneal dialysis,<sup>14,15</sup> the artificial kidney in its various forms,<sup>16,18</sup> and different types of intestinal dialysis,<sup>16,19</sup> Black and Stanbury fall back on what seems little more than a return to the old purging method. If anuria persists "for more than a few days" they recommend that intestinal dialysis with a slightly hypertonic solution of sodium sulphate should be carried out, to overcome the difficulty of sucking the solution back from the distal end of the duodenal tube they suggest that the washings should be collected through a wide-bore rectal tube. While it seems certain this is an effective method, the procedure shares the defects of all the dialysis methods in that, unless considerable care is taken, gross disturbances of water and electrolyte balance may result. Deficiencies or excess of sodium chloride or potassium may occur with any method, and to be safe, dialysis should always be supervised by a trained team with adequate facilities for chemical analysis. Other forms of therapy such as the use of diuretics and alkalinization have had their advocates, but Black and Stanbury conclude that they are potentially dangerous or ineffective. They do not comment on Peters's suggestion<sup>20</sup> that the kidney should be decapsulated. Convincing evidence that this is an effective method of therapy is still lacking.

## ANTIBIOTICS FROM STREPTOMYCES

At least five antibiotics of considerable interest are now known to be produced by various species of streptomyces isolated from soil. Streptomycin has already found its place in medicine, streptothricin is probably of little practical value. There are three others of importance, grisein, chloromycetin, and aurcomycin. Grisein is the name given by Reynolds and Waksman<sup>1</sup> to a new antibiotic derived from certain strains of *Streptomyces griseus*. This substance develops in surface and submerged cultures of the streptomyces: it is quite distinct from streptomycin and is unaffected by sulphhydryl compounds or carbonyl groups. The antibacterial spectrum is very similar to that of streptomycin and streptothricin, but is considerably narrower, and organisms that are resistant to streptomycin are not

necessarily resistant to grisein. Resistance to grisein seems to develop more rapidly than that to streptomycin, a finding which limits its value in chemotherapy. However, the addition of grisein in small amounts to streptomycin solutions has a synergistic effect on organisms sensitive to both antibiotics and appears to retard the development of resistant strains. As grisein is well tolerated by animals and is also active *in vivo* against organisms which are sensitive to it *in vitro* it may well be of value in supplementing streptomycin therapy by suppressing the rapid development of resistance in certain strains of coliform bacteria.

We have already drawn attention in a leading article<sup>2</sup> to the chemotherapeutic possibilities of chloromycetin. In addition to its action on rickettsial infections it now seems that chloromycetin may become the drug of choice for the treatment of typhoid, a disease which up to the present has not been amenable to treatment with either sulphonamides or antibiotics. Woodward and his colleagues<sup>3</sup> in Malaya treated with oral chloromycetin ten cases proved to be due to *Salmonella typhi*. The initial dose was 50 mg per kilo of body weight; thereafter 0.25 g was given every two hours till the temperature was normal, and the same dose was continued every 3 to 4 hours for the first 5 days of normal temperature. The total dosage averaged 191 g in 81 days. The drug was well tolerated and no clinical evidence of toxicity was noted. The blood level of chloromycetin during the first 24 hours averaged from 40 to 80  $\mu\text{g}$  per ml, and 20  $\mu\text{g}$  during the next three days. *Salmonella typhi* is inactivated *in vitro* by 0.25  $\mu\text{g}$  per ml. In ten treated cases, all in the first two weeks of fever, the mean duration of fever was 3.5 days after treatment. All blood cultures 5 days after beginning treatment were sterile, but positive stool cultures were observed in two patients up to the twelfth day of convalescence. Two of the ten patients relapsed with bacteraemia after afebrile periods of 10 and 16 days respectively, but the recurrences were promptly controlled in 2 and 3 days by second courses of chloromycetin. No evidence was found that the typhoid bacilli had become resistant to chloromycetin. Two serious complications were seen. One patient had an intestinal perforation on the second day of normal temperature; the second had a massive intestinal haemorrhage on the fourth afebrile day. Both patients recovered. Eight cases were used as controls. One patient died on the seventeenth day, and the average duration of fever was 35 days. Further studies on the effects of chloromycetin in typhoid and paratyphoid will be awaited with interest.

Aureomycin is a new antibiotic derived from *Streptomyces aureofaciens*, its antibiotic action has been described by Brer and his colleagues<sup>4</sup>. It is a yellow crystalline salt, supplied as a hydrochloride. It is soluble in distilled water but rather less soluble in isotonic sodium chloride solution; the solutions have a pH about 4.5, and in alkaline solution the activity of the antibiotic deteriorates rapidly at room temperature. Both Gram-positive and Gram-negative organisms are inactivated *in vitro* in broth: haemolytic streptococci by from 0.3 to 1.25  $\mu\text{g}$  per ml, pneumococci

by 0.1 to 0.3  $\mu\text{g}$  per ml, staphylococci by 0.6  $\mu\text{g}$  per ml, various strains of *Bact. coli* by 50  $\mu\text{g}$  per ml, Friedlander's bacillus by 1.0 to 5.0  $\mu\text{g}$  per ml, *H. influenzae* by 2.0  $\mu\text{g}$  per ml, *Brucella suis* and *Br. abortus* by 0.75  $\mu\text{g}$  per ml. Strains of proteus and *Ps. aeruginosa*, however, are not affected by 200  $\mu\text{g}$  per ml. Human serum seems to have an inhibitory effect on the antibiotic activity of aureomycin, which is bacteriostatic rather than bactericidal. If the broth contains 50% serum the concentration of the drug has to be increased about fifty times in order to bring about inhibition.

Patients suffering from coliform and *Str. faecalis* infections of the urinary tract, typhoid fever, brucellosis, and Rocky Mountain spotted fever have been successfully treated with aureomycin. The usual oral daily dosage varied from 10 to 60 mg per kilo of body weight given in six to twelve doses. Intramuscularly a total of 3 mg per kilo of body weight per day has been given, but signs of local irritation were seen. Five patients with Rocky Mountain spotted fever were all asymptomatic and afebrile in 12 to 72 hours, and a patient infected with chronic brucellosis due to *Br. suis* was afebrile three days after aureomycin therapy was begun.

## THE CHEMOTHERAPY OF UNDULANT FEVER

The chemotherapy of brucella infections has for long been a difficult problem. Even before the advent of sulphonamides it had been claimed that injections of neoarsphenamine occasionally worked like a charm, but in other cases they failed completely. There were strong hopes that the sulphonamides would be effective, but though temporary benefit occurred and some patients were apparently cured there was no clear evidence that the drug treatment had anything to do with the fall in temperature and the cessation of symptoms, since undulant fever is a self-limiting disease which after a shorter or longer period cures itself. It is now generally agreed that no sulphonamide by itself is able to cure any great proportion of cases. Possibly sulphadiazine accompanied by multiple blood transfusions, as originally proposed by Huddleson<sup>1</sup> and reported on by Holmes and Hughes,<sup>2</sup> may give rather more consistent results. Penicillin also is without effect on brucellae, and attempts to cure patients with it have failed. The sensitivity of brucella organisms to streptomycin was first demonstrated by Jones and his colleagues,<sup>3</sup> but earlier reports of treatment from the U.S.A. were disappointing. Only Finch<sup>4</sup> has claimed excellent results; he treated six patients with total doses of streptomycin varying from 20 to 51 g in 5 days. It is noteworthy that of his six cases five were due to *Brucella suis* and only one to *Br. abortus*. In addition, each patient received 500 mg of ascorbic acid daily.

The possibility of obtaining an additive if not a true synergic effect by combining sulphadiazine and streptomycin in the treatment of undulant fever was first explored by Eisele and McCullough,<sup>5</sup> who reported the results in a single case. Pulaski and Amspacher<sup>6</sup> and Pulaski and Seeley<sup>7</sup> treated six patients by the same method, though with smaller doses of sulphadiazine; two of their patients

relapsed. In this issue of the *Journal* Dr E F Scowen and Professor L P Garrod describe the treatment of two further patients with the same combination of drugs. The results in both cases were excellent, though it is not claimed that the best scheme of dosage has yet been worked out. Further results, however, will be awaited with interest. In the meantime it is worth while drawing attention to the remarkable experimental results obtained by Cotton and Swope<sup>6</sup> with *para*-aminobenzoic acid and sodium *para*-aminobenzoate. In guinea-pigs inoculated with a virulent strain of *Br abortus* a 5% solution of the soluble sodium salt given subcutaneously in doses of 5 ml every four hours for 21 days completely eradicated infection when treatment was begun 3 days after the infective dose had been administered. When treatment was delayed for 2 weeks after infection 8 out of 10 animals were cured. *In vitro*, the growth of *Br melitensis*, *Br suis*, and *Br abortus* is inhibited by *para*-aminobenzoic acid in a concentration of 2 mg per ml of tryptose agar medium. There is hope that a satisfactory treatment of brucella infections may at long last be in sight.

### PHYSIOTHERAPY

The exact organization of physiotherapy under the National Health Service has not yet been announced, but it is certain that physiotherapists will play their part in the Service. The great majority of practising physiotherapists are members of the Chartered Society of Physiotherapy, but their numbers would seem insufficient to fill all the posts that will become available, the recruiting of enough physiotherapists with adequate training and professional standards will therefore present a problem. The Chartered Society has always shown itself to be progressive and aware of the problems of the moment, and there is no doubt that it has made its preparations to meet the calls which will be made upon it. At a time when a new situation has to be faced it would seem opportune to review the relationship which exists between medicine and physiotherapy. Members of the Chartered Society are pledged to work only under medical instruction. That this pledge is not always honoured is to some extent the fault of the medical profession. Doctors very frequently order physiotherapy but seldom take the trouble adequately to instruct the physiotherapist, and the patient may be advised merely to "go and have some massage". Such an attitude is naturally unsatisfactory to a professional body whose aim it is to work in close conjunction with the medical profession. Furthermore, while it is the avowed aim of the Chartered Society always to work under medical direction, doctors are not always careful to select members of the Chartered Society to carry out their work and may not inquire into the qualifications of the masseuse to whom they send their patients. In the British Medical Association's report, *The Training of a Doctor*,<sup>1</sup> the following comment is quoted in paragraph 394: "Physical medicine is frequently prescribed but seldom understood".

In these circumstances it is not surprising that the Chartered Society may sometimes tend to adopt an attitude of less dependence on the medical profession. Physiotherapists have left the Board of Registration of Medical Auxiliaries, probably for good reasons, but now it seems that they intend to recognize prescription of treatment by members of their Society on a doctor's diagnosis. Hitherto both diagnosis and prescription

have been the sphere of the doctor, while the technique and practice of treatment have rested with the physiotherapist. This again is contrary to the B.M.A. report, in which it is stated, "Physiotherapists are highly trained technicians, diagnosis and prescribing are no part of their duties. Doctors would certainly be shirking their responsibilities if after making a diagnosis they handed over their patients to auxiliaries for prescription."

Under the National Health Service physiotherapists will presumably form part of the therapeutic team led by the doctor. But team-work will not be easy if the members no longer think along the same lines. Pathology connotes one thing to the doctor, to the physiotherapist often quite another. Physiotherapists are taught their medicine by their own teachers. It is understandable that to the physiotherapist the treatment of rickets and lupus vulgaris is general and local ultra-violet irradiation, despite the potent remedies available in vitamin D and calciferol. But it is less understandable that to the physiotherapist the treatment of gout is lithium ionization, when the use of lithium in any form is rejected by no less an authority than Professor Henry Cohen.<sup>2</sup> "Hepatic massage" is advocated for right heart failure in a book<sup>3</sup> written for physiotherapists by a teacher of physiotherapy and published in 1948. Similarly 'abdominal massage' is advocated for "gastritis". There are other instances which might be taken to indicate that physiotherapy is establishing a pathological and therapeutic system of its own and is tending to follow the footsteps of chiropractic and osteopathy. Such a possibility is remote. Nevertheless the time is ripe for the closer co-ordination of medicine and its handmaiden physiotherapy. Good will on both sides will easily achieve this, and since physiotherapy is on the eve of great expansion this co-ordination should be fostered and encouraged by both the Chartered Society and the medical profession.

### TUBERCULOSIS AND VOLUNTARY ACTION

Last week the National Association for the Prevention of Tuberculosis celebrated the fiftieth anniversary of its foundation by King Edward VII, who, as Prince of Wales, called an informal gathering of medical men at Marlborough House and launched what has proved a most successful scheme. The NAPT remains a voluntary body, and its policy is to encourage research and to seek public support for all measures which may help to suppress the disease. In the National Health Service there is a definite place for the non-official agencies which are interested in the prevention of tuberculosis. In this field the NAPT has been the leading organization. The next ten years should see no restriction of its activities. We have already remarked in a leading article<sup>1</sup> that the prevention of tuberculosis might well form the main task of medical officers of health now that they are freed from routine hospital administration, and their work will be made easier if the interest and sympathy of the public are maintained by the NAPT and similar voluntary agencies. The NAPT can truly call itself a "voluntary" body, for it receives no money at all from Government sources and is financed entirely by public subscriptions. It is now extending its activities to the British colonies where the scope for pioneering work is as wide as it was in this country 50 years ago. The Jubilee issue of the NAPT *Bulletin* has been published this month, it contains a message of congratulation from the King and from many distinguished persons in this country and abroad, including the chairman of the Council of the British Medical Association.

## HEALTH REGULATIONS FOR AIR TRAVEL (II)

BY

J KYLE

*Air Commodore, R A F (ret) Assistant Director of Medical Services British Overseas Airways Corporation*

In the first article on the above subject (*Journal* 1947, 2, 741) Dr Barrett focused the attention of practitioners on quarantine procedure in air travel as it affects general practice to day. It is felt that, having read that article, medical practitioners may well ask where they are to find current quarantine requirements and how they are to keep themselves informed of any future variations. An endeavour is made in the following paragraphs to answer these questions as briefly and clearly as possible in a limited space.

The provision of inoculation and vaccination certificates against one or more of the following diseases—smallpox, yellow fever, cholera, plague, and typhus—is, as a rule, an essential part of the formalities of air travel, and passengers are informed of their particular immunization requirements at the time of booking. Under normal epidemiological conditions these remain fairly constant, and, so far as the routes operated by British Overseas Airways Corporation are concerned, are here tabulated.

It is of assistance to the passenger for the practitioner to check any existing certificates to ensure that they conform to the requirements of the route along which he proposes to travel and, if necessary, to inoculate him afresh and issue new certificates. The wise traveller should take no avoidable risk in playing for absolute safety in this respect, and certainly will not do so if he has any experience of the delays that are apt to occur. In all cases it is essential that the international form of certificate recommended by the International Sanitary Convention

for Aerial Navigation, 1933, as amended in 1944 (which may be obtained from the Ministry of Health, Section 5C, Whitehall, SW 1) should be used.

The outbreak of cholera in Egypt in the autumn of 1947 emphasized the need for compliance with new quarantine regulations immediately they are issued. In the present state of the world, both politically and from the epidemiological angle, new restrictions and/or variations of existing ones must be anticipated. Amendments to quarantine requirements are notified to the British Overseas Airways Corporation by "Line" authorities immediately and by World Health Organization and the Ministry of Health weekly, and the Editor of the *British Medical Journal* has kindly agreed to publish them in the *Journal* as necessary, in order that practitioners may keep themselves up to date on the subject.

These notes and the accompanying Table are not the complete picture of immunization for air travel, but only a practical guide to actual route requirements based on a continuous scrutiny of the current quarantine regulations in all those countries or areas which B O A C or British aircraft transit. It will be appreciated that it is the right of each individual country to enforce quarantine restrictions on its airports at its discretion, and it will be apparent therefore that one country alone, doing so, out of perhaps six or eight transited, means that a certificate of immunization is required for all travellers along that particular route. Moreover, the validity of a certificate, as regards either its commencement or cessation and even the dosage of the vaccine or serum to be used, varies among the countries which have signed the Convention.

A chart indicating all these details and variations in requirement for embarkation, disembarkation, and transit, and the actual countries declared infected by the quarantining country is maintained up to date, and provides the source of supply of information for inquirers, but it will be understood that such a chart is too elaborate and extensive for reproduction in this article.

*Passenger Protective Requirements for Specific Routes from England and Return Including Stopping Places on Each Route (Revised November 19 1948)*

	Route	Yellow Fever	Smallpox	Cholera	Typhus	Plague	T A B	
No 1 Line } No 2 Line } No 4 Line }	London-Cairo Cairo-London Southampton-Alexandria Alexandria-Southampton	— — — —	Yes R R R	R R R R	R R R R	R R R R	R R R R

No 4 Line	Southampton-Sydney Sydney-Southampton	R R	Yes Yes	Yes Yes	R R	Yes Yes	Yes Yes	
No 4 Line	Southampton-Bahrain Bahrain-Southampton	— —	Yes Yes	R R	R R	R R	R R	

"Yes" indicates that the inoculation or vaccination is an essential requirement without which the passenger will be held in quarantine on arrival or may not be permitted to embark.  
— indicates there is no requirement.  
R indicates that owing to the presence of the disease or other circumstances the inoculation or vaccination is desirable for the passenger but it is not an essential requirement.

Protective inoculations against major epidemic diseases are required as follows: Smallpox for practically all routes. Yellow fever for journeys to and from West and South Africa. Cholera for all journeys to and from India and Far East. It is also advisable to be protected if en route to West Africa and Egypt. Typhus and typhoid group (T A B C) for these diseases protective inoculation is recommended though not essential on all routes. For journeys from some airports in the Orient.

## Nova et Vetera

### THE LIBRARY OF CALEB HILLIER PARRY

Mr Reginald W M Wright, city librarian of Bath, has lately published in the *Record-Bulletin* of the municipal library (1948, 1 225) an account of the Bath Hospital Medical Library. The library has been under his care for many years, and has now been formally presented by the hospital to the city. Bath has been famous as a health resort since Roman times. It is therefore right that the city should own a medical library. But this library has the special value that it was formed by Caleb Hillier Parry, the great Bath physician who made valuable observations on the cause of angina pectoris and described the syndrome of exophthalmic goitre. At his death in 1822 Parry bequeathed to the Bath Hospital his collection of 555 medical books covering a remarkably wide range of history. His successor as physician to the hospital, Dr John Soden, added a further 220 books when he died in 1863.

Parry's library contains many Renaissance books, both texts of the Greek and Arabic medical writers and original works of the sixteenth century. It is instructive to find that he owned works of English medical writers of the Tudor period, such as Elyot, Borde, Vicary Peter, Lowe and William Clowes, who are generally thought to have been despised in Parry's time. The library is also broadly representative of European medicine of the seventeenth and eighteenth centuries.

Edward Jenner was one of Parry's intimate friends. He dedicated his *Inquiry into the Cow-pox* to Parry, and a copy of the original edition of 1798 is in the library. Twenty-four years later Jenner published *A Letter to Charles Henry Parry* (Caleb Parry's son), his presentation copy is also in the library. The elder Parry's own writings are fully represented; he was an agriculturist and geologist as well as a physician.

## Reports of Societies

### FOOD-POISONING

A meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine was held on Dec 6, with Sir ALLEN DALEY, the president in the chair.

Dr E T CONYBEARE opened the discussion with a reference to the pioneers in this branch of preventive medicine (notably Ballard and Savage) the former considered that cleanliness in food handling would by itself eliminate these diseases while the latter stressed the importance of the reservoirs of infection, especially of salmonella diseases. The recent increase of food poisoning outbreaks in this country, which began about 1942 and has continued since, was doubtless attributable in large measure to increased consciousness on the part of doctors and patients of the importance of even mild or missed cases in causing spread and to better laboratory facilities for diagnosis but there was reason to believe that there had been an actual increase due to greater use of prepared foods and to storage of food in homes where there were no proper facilities. Although the current Ministry of Health memorandum was now obsolete and should be revised, it remained a moot point whether further progress might be expected to result from fresh legislation, which was most applicable to the control of large scale food manufacture and catering. In relation to personal hygiene and to the smaller units engaged in food distribution, legal powers such as those available in the Food and Drugs Act 1938 though useful were less effective. It might well be that education in personal and domestic hygiene as foreseen by Ballard sixty years ago, was the only real precaution against food poisoning.

Dr V D ALLISON outlined the different factors in the wartime increase of food poisoning: the use of synthetic cream, cooked meats including sausages, shortages of hot water, soap, towels and crockery which too often was cracked, and the

employment of insufficiently trained kitchen staffs. Contamination with staphylococci was a not uncommon cause of food poisoning. It was characterized by a short incubation period (one to seven hours, average three hours), acute onset with abdominal pain, nausea, vomiting and often diarrhoea lasting three to twenty-four hours, and this was followed by rapid recovery even in those cases in which there were symptoms of collapse. Recent surveys had shown that 50% of normal adults harboured such organisms in the nose, and in some 10-20% they were present on the skin of the hand. The current accepted criterion of actual or potential pathogenicity among staphylococci was the ability to produce plasma coagulase. The organisms could be identified by serological and bacteriophage techniques, but these methods were as yet inapplicable to routine laboratory and epidemiological investigation. Human volunteers and suitable workers were still necessary for proof of pathogenicity. When the organism had been destroyed by cooking or processing (leaving the toxin intact, as it resisted boiling even for thirty minutes) the difficulties were great, as the kitten test for enterotoxin was no longer accepted in many cases the evidence was no more than circumstantial.

Dr JOAN TAYLOR discussed the salmonella group and recent work on the identification of strains. These organisms were generally resistant to specific therapy and persisted in the gut longer than was formerly thought. An animated discussion followed in which current practice in food handling, including the routine inspection of meat, was severely criticized. The need for education in the school and by means of the Press, radio and film was stressed.

### DEEP PAIN SENSIBILITY

#### MANCHESTER MEDICAL SOCIETY

At a meeting of the Manchester Medical Society on Dec 1, Dr J H KELLGREN delivered an address on "Deep Pain Sensibility." He said that the phenomena of pain were usually described in terms of distribution, time, intensity, and relation to other phenomena such as movement and rest. Not all the differences between one pain and another could be described in these terms only, for there were three main types of pain that could be distinguished by their qualities: deep pain arising in muscles, bones and joints, and cutaneous pain, which might be immediate or delayed. The delayed pain had an "itch" component which gave it a distinctive quality. These three types of pain sensibility could be dissociated in disease or by nerve blocks, so they were probably mediated by different types of nerve fibres.

The normal sensory gradation which accompanied a graded stimulus might be lost so that a threshold stimulus set up severe prolonged pain. This explosive exaggerated response affected all three types of pain, and such terms as 'protopathic,' 'hyperpathia,' and 'peculiarly unpleasant' probably described this phenomenon rather than an alteration in quality.

The deep tissues varied in sensitivity to pain. In the less sensitive tissues pain sensitive spots were infrequent, varying sensitivity of the tissues probably resulted from a varying density of innervation. Pain from deep tissues was also localized with varying accuracy. Thus subcutaneous periosteum, ligaments and fascia gave rise to local pain while structures lying deeply within the trunk and limb girdle caused diffuse pain of segmental distribution. Intermediate structures gave rise to segmental pain more or less modified by a crude attempt at localization. The areas of cutaneous hyperalgesia occasionally found in visceral disease were entirely different phenomena from deep pain of segmental distribution; it was a misstatement of fact to say that pain was referred to this or that dermatome because segmental deep pain was felt in the deep structures and not misinterpreted as arising from the skin. The possible mechanisms of pain localization and referral were then discussed.

Deep pain was accompanied by segmental muscle spasm. This spasm had been studied in decapitated cats and found to be produced by a spinal reflex. Electromyographic studies in diseases such as sciatica, rheumatoid arthritis and fibrositis often revealed this type of muscle spasm. Its presence had been held to support the view that these diseases were primarily

neurogenic, but the only conclusion that could be drawn from these findings was that the subject's pain was deep, since cutaneous pain was not accompanied by this type of muscle spasm. Of more interest was the possibility that this continuous motor activity might lead to muscle fatigue and so to secondary sources of pain.

#### Effect of Cooling

Deep pain sensibility was peculiarly susceptible to cooling. Cooling tissues rapidly caused severe pain while the temperature was falling from 30° to 15° C, but with further cooling the pain faded away because deep analgesia developed, becoming complete at about 10° C. With slow cooling analgesia was effected without preceding pain so that the usual climatic fluctuations of temperature gave rise to no pain in the normal individual. If deep hyperalgesia was present, even slow cooling of the affected part might cause prolonged and severe pain and the analgesia developed imperfectly. Pain produced by cooling and relieved by warmth was a feature of many conditions affecting the extremities: post-traumatic syndromes, painful nerve injuries, glomus tumours, and many forms of arthritis and rheumatism. In these cases the cold pain was mainly due to abnormal sensitivity of the deep pain nerves, though vascular disturbances might contribute to the symptoms by allowing abnormal cooling.

Dr Kellgren concluded that deep pain sensibility had certain attributes such as characteristic quality, frequent false localization, associated muscle spasm and susceptibility to cooling which distinguished it quite clearly from cutaneous pain. Deep and cutaneous pain sensibility might be dissociated, so they were probably mediated by different types of nerve fibres. Furthermore, the clinical syndromes produced by disturbances of deep and cutaneous pain sensibility might differ markedly, and what was true of cutaneous pain was not necessarily true of deep pain. It would therefore seem wise to distinguish between these two main types in all clinical and experimental work.

A brisk discussion followed in which Professor Schlapp, Professor Jefferson, Professor Morley, and Dr Marshall took part.

#### FACIAL PALSY

A meeting of the Liverpool Medical Institution was held on Nov 25, with the president, Professor T P McMURRAY, in the chair.

Mr R P OSBORNE said that, whatever the cause of facial paralysis if signs of recovery were not manifest within four months support to the paralysed side should be provided by means of fascia lata slings. The view that plastic surgery was only of value when the paralysis was deemed permanent was incorrect. Many of the results of other procedures—for example, nerve grafting—were spoilt by the stretching of the muscles which occurred during the long interval, possibly two years, before return of function. No matter what operation was contemplated on the nerve itself the provision of a fascia lata sling at an early stage could do nothing but good. In cases in which operation on the nerve was not contemplated the insertion of fascia lata slings would not prevent full recovery where this was possible and would tide over the period of stretching which would otherwise follow. The difficulty was in finding some exact method to decide whether recovery was probable and whether it would be progressive. The ordinary faradic test was too crude for this purpose. Electromyography while still in its infancy showed signs of being a much more delicate and reliable means of obtaining the necessary information.

At the same meeting Mr D ANNIS read a short paper on experimental pancreatico gastrostomy.

On Dec 10 and 11 the Fever Hospitals Medical Services Group of the Society of Medical Officers of Health held a week-end meeting at the North Eastern Hospital, St Ann's Road, N 15. The president of the Group, Dr E C BENN (Leeds), was in the chair. On Friday Dr J E FRANCIS read a paper on palatal paralysis in children. Dr F O MACCALLUM spoke on the laboratory diagnosis of some virus infections and Dr N H BRADLEY presented a film on poliomyelitis. In the afternoon Dr M B ALEXANDER discussed infantile diarrhoea and vomiting and Dr JOAN TAYLOR read a paper on recent research on the aetiology of infantile enteritis. On

Saturday the subject for discussion was the role of the nasal carrier in the spread of infection. Dr G W RONALDSON spoke on the carrier of diphtheria, Dr R CRICKSHANK on the carrier of haemolytic streptococci, and Miss WINIFRED HALL on the treatment of the nasal carrier.

## Preparations and Appliances

### DAYLIGHT SCREENING AID FOR MASS RADIOGRAPHY

Dr S W VIVIAN DAVIES, Assistant Medical Director, Mass Radiography Unit, Warwickshire and Coventry Joint Committee for Tuberculosis, writes: With the accommodation placed at the disposal of mass radiography units it is not always possible to get a satisfactory black-out for screening

purposes. The factories concerned are already subsidizing the running of the set at their premises, and anything which reduces the cost and also the difficulties of preparing accommodation is of advantage. Moreover, on public surveys large halls have often to be used where an adequate black-out is impossible. Further, it is necessary to have the staff working in as natural a light as possible.

I have therefore devised a simple radioscopy hood, which I have now used on several surveys and have found very satisfactory. The materials employed are four 18 by 1 1/2 by 1/4-in (45 by 3.75 by 0.6 cm) pieces of ebonite 2 yards (1.8 m) of thick black-out non-coupon material and eight small nuts and bolts. The accompanying diagrams will give sufficient details for making one of these hoods. A frame is constructed to correspond with the camera tunnel, the slot-holes, etc., being made to measure. The hood material (black-out), in double thickness, can then be sewn round the frame with buttonholing to match the slots. To exclude light a draw-string is used in the skirt of the hood.

When using this device I have found that the patient being screened is less apprehensive and more co-operative, thus materially compensating for its defects.

A collection of over 300 surgical instruments given for use in Scottish hospitals during the war by the late Mr J Hogarth Pringle has been handed over by the Department of Health for Scotland to the Glasgow Royal Infirmary where it will be housed to commemorate Mr Pringle's services there and his patriotism in making the gift. Mr Pringle presented his valuable collection to the Department in January, 1940, when Scottish hospitals were seriously short of surgical instruments in response to an appeal made by the Rt Hon Thomas Johnston, then the Regional Commissioner for Scotland. It was arranged that the collection be permanently associated with his name and used at a Scottish emergency hospital, and the instruments were used at Gleneagles Hospital for some years. When the hospital was closed they were returned to the Department, and they have now been accepted by the Glasgow Royal Infirmary, where Mr Pringle was in charge of the surgical wards for 27 years.

these unfortunate women are subjected, often with no greater success. May I conclude, therefore, by saying that not only are their criticisms inaccurate but Drs Moore White and Friedmann have missed the object of my article. I have described a simple plan which, without any other treatment or investigations, appears to be followed by a sufficiently high percentage of successes to justify it being tried, if not alone at least whilst awaiting the propitious moment for the carrying out of diagnostic tests—I am, etc.,

## REFERENCE

1 *J Obstet Gynaec Brit Emp* 1938 45 932**A Sign of Pregnancy**

SIR—I am grateful to Dr Albert W Bauer and Mr Keith Varlan (Nov 27, p 956) for their letters with regard to Piskacek's sign. I had felt that it was a sign which, when recognized, was so unmistakable that it must have been described previously, although I had been unable to find a record of it. In addition to the references quoted in these letters Professor R A Lennie and Dr A S Duncan have drawn my attention to an account of the condition in Munro Kerr's textbook.<sup>1</sup> This, however, makes no reference to Piskacek.

Although the sign appears to be fairly widely known, it is by no means as generally recognized as perhaps it ought to be and my old friend and teacher, Dr W F T Haultain, assures me that the danger of taking such a swelling for a large cystic ovary or even an extrauterine gestation was such that it used to be said that no one was a real gynaecologist unless he had opened a pregnant abdomen owing to such a mistaken diagnosis. Dr Haultain disagrees with my assertion that examination under anaesthesia will reveal the true state of affairs, since even under anaesthesia the gynaecologist has very often been "had for a mug." Perhaps this correspondence, by reviving interest in the sign, as Dr Bauer suggests, may help to prevent some further instances of this error—I am, etc.,

## REFERENCE

1 *Combined Textbook of Obstetrics and Gynaecology* 1944 p 291 Edinburgh E. and S. Livingstone**Syringe-transmitted Jaundice**

SIR—Dr R S Morton is to be congratulated on his courage in writing an article (Nov 27, p 938) which is a salutary reminder that the medical officer in charge of the conduct of the session is responsible not only for the clinical aspects of the work but also for seeing that all the available precautions and safeguards to prevent untoward happenings have been religiously observed but alas, "The best laid schemes of mice and men."

In the past the standards of sterilization were dangerously inefficient in some clinics, and yet jaundice rates of the order observed by Dr Morton did not occur vice versa, in departments where the technique employed left nothing to be desired outbreaks occurred sporadically. The incidence in the series of cases reported on is so remarkable (20.7–33.6%) as to suggest a local epidemic. From the information given it is impossible to separate Dr Morton's series into cases of (a) possible infective hepatitis, and (b) possible homologous serum jaundice. Differentiation into these groups would have been of value. The first group is obviously related to the incidence of jaundice in the general population of the clinic catchment area. It would therefore be interesting to learn the incidence of hepatic infection in the households of the cases quoted, also whether any infections occurred in the members of the clinic staff or in patients not undergoing injection therapy. Dissemination of hepatitis by droplet infection a possibility often ignored these days can occur as is instanced by the following case.

A few months ago a patient on sero surveillance for syphilis, reported with jaundice. Some 2–3 weeks previously he had had a blood test and reporting for the result two days later he met and had a long conversation in the waiting room with two seamen. These patients were traced (original diagnosis presumably gonorrhoea), treated aboard ship with minimal doses of sulphathiazole and having no serological tests and found to be jaundiced on examination. In view of their general condition no tests were taken, they were advised to return when the jaundice had been treated.

In recent years there has been little epidemic jaundice among the general population in Bristol, consequently jaundice has rarely appeared in the clinic.

One would also question the role of a hepato-toxic drug in the precipitation of jaundice in a patient subclinically infected. It is inferred that serological tests, penicillin, and heavy-metal injections are carried out in parts of the Newcastle General Hospital clinic other than in the medical officer's room. It would be interesting to learn of the incidence of jaundice occurring in patients "needled" there, for it appears from the paper by Dr Malmros and his colleagues (Nov 27, p 936) that intramuscular injections and venepuncture for serological testing are equally suspect. Finally, the inclusion of comparative rates for a series of cases showing the effect of the resolute application of the measures advocated would have completed the pointing out of the obvious moral—I am, etc.,

Bristol

DONALD D BROWN

**Corneal Graft Surgery**

SIR—Dr F W Simpson (Dec 4, p 999) tells us that as a result of the New York eye bank thousands of corneal grafts have undoubtedly restored vision to many blind people and that there ought to be a bank in Britain. The excellent work of the American eye bank has been watched with great interest, but the idea is not new to British ophthalmologists. Mr Tudor Thomas initiated a similar project before the war at the Central London Ophthalmic Hospital.

Corneal-graft surgery, however, is not yet practised here as widely as it should be, nor to the extent that it is in Switzerland and the United States. There are many reasons—namely (1) Apart from an interested few British ophthalmic surgeons on account of war service and conditions have not had the opportunity to acquire the special experience necessary for this operation, which is one not to be undertaken lightly. (2) Judicious caution, therefore, has had to limit the indications which British surgeons consider justify the operation. Swiss and United States oculists, on the other hand, by virtue of greater experience and practice have been able to expand the scope of their graft operations, and have used them with success in cases which would be treated here by more conservative, though less effective, measures such as optical iridectomy. (3) The success of a corneal-graft operation is much influenced by perfection of instruments. In Great Britain there is an overall shortage of all eye instruments and needles. British instrument manufacturers are hard pressed to turn out special corneal-graft instruments in any quantity, as they are already weighed down by orders for routine eye instruments and likely to become more so. (4) There is no systematic practical course of instruction in corneal-graft surgery in this country, although there are occasional postgraduate demonstrations. These demonstrations do much to whet appetites for the operation, but they do little towards individual basic instruction in technique. At the last postgraduate demonstration at the plastic unit, East Grinstead over 30 students were striving to peer from gallery and floor at the manoeuvres being carried out on an area about 5 mm square.

Therefore, in my opinion the expansion of corneal-graft surgery in this country requires more than the establishment of an eye bank. Our distances are not great and, as yet, our cases do not run to "thousands," nor is there much difficulty at present in obtaining a living or preserved graft. However, if we are to draw abreast of our colleagues abroad, corneal-graft surgery must be treated as a subject of routine instruction in the surgery of ophthalmology. Courses of instruction will draw support from an eye bank and future research will come to be based on it—I am, etc.,

B W RYCROFT

**Procaine Penicillin**

SIR—I read with great interest the article by Drs P F Jones and R A Shooter (Nov 27, p 933) on the use of procaine penicillin. I think your readers may be interested to read of its use in general practice. I have used it in three cases and it has been most successful in its action.

The first case was a man with an abscess of the left inner canthus. The eye was closed, and he was in great pain. He received

ml of procaine penicillin G containing 300,000 units daily for four days. On the second day he volunteered the information that there was no pain felt at the injection site and the abscess was no longer painful. After the four injections the eye was healing well and a week later was normal.

The second case was a woman with a carbuncle of the forearm which was 2 in. in diameter. She received four daily injections of 300,000 units of procaine penicillin G, and she remarked on the complete absence of discomfort at the site of injection in contrast to injections of penicillin received on previous occasions. Within five days the carbuncle site was almost unnoticeable.

The third case was a man with an infected pulp space who had had his finger incised at a county hospital with local anaesthesia, followed later with a general anaesthetic and a thorough incision of the pulp. The finger was very painful and swollen, and there was an abundant discharge of pus. The man had toxic symptoms. He received three daily injections of procaine penicillin G (300,000 units), and after three days the finger was healed on one side and almost healed on the other. There was no pain and he felt very well.

As advocated by Jones and Shooter, a No. 1 serum needle was used to take up the penicillin and a No. 1 hypodermic needle was used to administer it. A 20 ml. syringe was used as the suction provided by a smaller syringe was found inadequate to provide the speed essential in a surgery. The site of injection was the lateral aspect of the thigh. It took 45 seconds to administer the 1 ml., with heavy pressure on the barrel of the syringe. A notable feature was the complete lack of pain or reaction at the injection site, and it was a great help to both patient and doctor to find that the patient was required to attend the surgery only once daily. The penicillin is not kept in a refrigerator and that, too, is an advantage in these days of shortages—I am, etc.

T. DAVID LAMBERT

### Antihistaminic Drugs and Radiation Sickness

SIR,—I would like to humbly comment on the paper with the above title by Drs W. M. Court Brown and R. B. Hunter (Dec 4 p. 984) in the following manner.

(1) The comprehensive title is not justified by the investigation of only one drug of this series.

(2) The toxic symptoms of 'anthisan' are similar to those of radiation sickness—that is, drowsiness, fatigue, headache, nausea, and vomiting. The drug was used in the test in very heavy dosage. As will be noted, seven patients were unable to endure the full 1 g. daily dose. Surely aggravation of these symptoms might simply have been caused by combining two measures so liable to produce the same toxic manifestations. In other words the results would be more convincing if smaller and thus less toxic doses of anthisan were employed.

(3) To suggest that histamine not only plays a part but actually effects a beneficial physiological reaction merely superimposes conjecture on the insecure foundation of hypothesis—I am, etc.

Leicester

JAMES OVERTON

### Hypertension Complicated by Tetanus

SIR,—The interest of the following case lies in the occurrence of a near malignant phase of hypertension during an attack of tetanus.

On April 29, 1948, a tractor driver aged 44 complained of difficulty in swallowing and severe head pains. On May 3 he had stiffness all over especially in the back, neck, and jaws with pains shooting down the back and constricting pains in the chest. He could not open his eyes fully, and he had difficulty in commencing urination. Cold sweats were another symptom.

His past history was as follows: morning headaches and faintness for past few months; 'gastric ulcer' some years ago; lacerated wound of nose from fall in a wood yard 7 months previously—wound healed within a few days without attention. No convulsant drugs had been taken.

He was admitted to hospital on May 5. There was severe rigidity of neck, back, abdominal and thoracic muscles; jaws and eyelids. A scarr, 1 in. long was present on his nose. Testes absent from undeveloped scrotum. Pulse rate 104, B.P. 220/150, no evidence of contraction of aorta. Retinae showed arteriosclerosis and recent exudates. Urine showed heavy albuminuria but no casts nor R.B.C. blood urea, blood counts, W.R. and C.S.F. were normal. X-ray showed left ventricular hypertrophy and aortic hypertensive changes.

Venesection on May 5 and 6 had no apparent effect. Blood pressures at various dates were: May 5, 220/150; May 7, 190/135.

May 8, 175/115; May 13, 165/110; May 24, 160/105; May 29, 170/120; May 30, 180/120.

An irregular pyrexia up to 101° F (38.3° C) commenced on May 7 and ended on May 12. Clonic spasms commenced on May 8, affecting the spinal muscles and jaws, resulting in a bitten tongue. By May 19 the clonic spasms were less frequent. On May 24 clonic spasm was not present and tonic spasm was receding. Retinal exudates were resolving. Urine now showed only a trace of albumin.

Rigidity had practically gone on May 29. Retinal exudates had completely resolved, the arteries remained tortuous, with linking of veins. Gravitational oedema was present, lungs clear, pulse rate 102, B.P. 180/120, Hb 95%, serum proteins, total 5.5 g (albumin 2 g, globulin 3.5 g), urea clearance normal, urea concentration test unsatisfactory owing to diuresis. Intravenous pyelogram showed only poor concentration of dye; a single large gallstone was seen in the gall bladder.

On June 16 the oedema was much less, serum proteins 6 g (albumin 4 g, globulin 2 g). Urine still showed a trace of albumin. The patient felt perfectly well.

Thus it appears in this case that tetanus precipitated a rise of blood pressure, an increase in albuminuria, and retinal exudates in a patient with essential hypertension, these changes being partly or wholly reversible—I am, etc.

Bishop's Stortford, Herts.

EMIL LEIGH

### Marxist Genetics

SIR,—Surely the important issue in this matter is not whether the opinions of Lysenko are or are not credible and satisfactory. The lamentable feature of the Soviet decision is that no criticism of these views is to be tolerated. Any scientist who may in future within the Soviet Union express any opinion contrary to the accepted Lysenko doctrine will be "dealt with" as an enemy of the State. The disaster is the prohibition of freely expressed opinions on a subject requiring research and investigation—I am, etc.

Bradford

JAMES PHILLIPS

### Fall of Blood Pressure after Pylolithotomy

SIR,—The following case appears to me to be of interest for two reasons, first because of the drop in blood pressure, and secondly on account of the absence of haemorrhage during the operation for the removal of a stone from the pelvis of the kidney.

A female patient aged 64 complained of headache and backache and was discovered to have a blood pressure of 240 systolic and 160 diastolic. On further investigation she was found to be suffering from a stone in the pelvis of the left kidney. Under a general anaesthetic the kidney was exposed and the stone removed. The operation was performed from beginning to end with an entire absence of haemorrhage, and not a single pair of Spencer Wells forceps was used. The patient made an uneventful recovery, and the blood pressure returned to normal and remained so for five years, when she left the district and I lost touch with her.

In my opinion the hypertension and the lack of haemorrhage at the operation were due to peripheral spasm of the blood vessels. The peripheral spasm was probably caused by the secretion of a pressor substance from the damaged kidney—I am, etc.

J. T. R. EDWARDS

### Breast-feeding

SIR,—Last night I was once more called out to see a baby screaming with pain and obviously suffering from colic. These cases are becoming more and more frequent, and this case was quite typical.

It was the usual story. The mother had her baby in a well-equipped municipal home. She was splendidly looked after: plenty of food, gas and air, wireless, marvellous food, and in her own words she could not have been treated better if she had been the Queen. Naturally breast-feeding was established, and she left the home after fourteen days. She was given full instructions and told there was no reason why she should not continue to feed her baby.

She returned to run her home, husband and invalid mother in law with no help. The milk does not come quite so freely and the baby cries a little at night. (She had no idea that the baby would cry at night, as she had never seen it during the silent hours.) Obviously she thinks her milk does not agree with it and she does one of two things. She either gives it a supplementary feed or takes

it off the breast entirely. In either case the end result is the same: the baby goes on to the bottle. In my experience the mother *never* consults a doctor, nurse, or infant welfare clinic at this stage, as she has no intention of accepting their advice. She has no experience of bottle feeding, and almost invariably the baby develops colic. The mother, father, and "in laws" become distracted, and at last the wretched G.P. is dragged from his bed. To coax the child back on the breast is almost impossible, and the family doctor embarks on a long and somewhat tedious demonstration of the "art" of bottle feeding. He knows that he will be blamed by the powers that be for another failure in breast-feeding.

The mother who has her baby at home with the midwife in attendance and perhaps the doctor does not have such a pleasant time, but she knows a good deal about the baby by the fourteenth day. She sees the baby bathed, she knows about its navel and its nappies, and she knows that it can (and does) cry at night. The doctor and midwife know the home conditions and know what chances of success there are in breast-feeding, and before they take their leave the mother knows she can and will breast feed or the baby is well established on the bottle (I know it's disgraceful, but it is so).

If we are to have self-reliant mothers and strong babies I maintain that maternity hospitals, etc., should be for complicated cases and mothers who simply cannot have their babies at home for lack of space or help. In these days of shortage of hospital beds and nurses, of long waiting-lists of old people existing under dreadful conditions and needing hospital treatment, there is no excuse for 10% of available beds to be filled with healthy mothers who would be much better morally and physically, in their own homes—and perhaps I shall not be dragged from my bed at 2 a.m. to see a baby with colic—I am, etc.,

Weymouth Dorset

ELLIS PARKINSON

SIR,—Dr J. S. Hill (Nov 20 p 919) considers that artificial feeding has no deterrent effect whatsoever on children's health. He reports as examples his own four bottle-fed children. It would be unwise to generalize on such a small series, however, and the following figures may be more to the point. Grice, Sanford, and Herron<sup>1</sup> studied 20,000 children under 1 year old in Chicago. Of 9,749 who were wholly breast-fed 15 died, of 8,600 partly breast-fed 59 died, and of 1,707 wholly artificially fed, 144 died. The morbidity rates (including minor infections) were breast-fed 37%, and artificially fed 63%. Assessing results from another view-point, Levi<sup>2</sup> reported 100 consecutive cases of breast-fed babies operated on for congenital pyloric stenosis at the Infants Hospital, Westminster, with no deaths. In the same period 46 artificially fed babies were operated on and five died (from gastro-enteritis). Is this enough "modern evidence"?—I am, etc.,

Bristol

#### REFERENCES

- <sup>1</sup> *J. Amer. med. Ass.*, 1934, 103, 735.
- <sup>2</sup> *British Medical Journal* 1941, 1, 963.

SIR,—The low incidence of breast feeding in this country is distressing but not surprising when one reads a letter from a maternity and child-welfare medical officer referring to it (Dec 4, p 994) as an "irksome tie". To establish satisfactory breast-feeding it is essential for the mother to accept it both antenatally and post-natally as the best and simplest way of feeding her baby. One must agree with Dr Grace Walker that babies are a tie, but fortunately in most cases not an irksome one. Husbands, wives and patients are also a tie, but the majority of decent people are still willing to give them the best that they can.

Psychologically, the chief asset of breast-feeding is that it ensures the mother feeding the baby herself and not handing him over to someone else or, worse still, propping the bottle up on a pillow. From my own observations I am convinced that the majority of breast-fed babies pass their "milestones" before the bottle-fed ones (I hope to be able to produce figures to substantiate this claim later). Medically the chief ailments of infancy are feeding difficulties and acute infections, particularly gastro-enteritis and respiratory infections. Feeding difficulties in a baby with whom breast feeding is established are almost non-existent. As you mention in your leading article (Dec 4 p 990) the greatest incidence of gastro-enteritis is among artificially fed infants. I have no

figures to quote for respiratory infections, but for general illnesses the fact that a 70-bedded general children's hospital provides only two beds for nursing mothers, and that those are more than adequate, speaks for itself. Dr Walker suggests that breast-fed babies suffer from lack of vitamins. I should like to point out that it is just as simple to give a teaspoonful of cod liver oil, etc., to a breast-fed baby as to a bottle-fed baby.

Leaving psychology and medicine, and writing as a housewife I am unable to understand Dr Walker's remark that breast-feeding is 'a primitive function which the majority of women find they cannot fulfil in the rush and bustle of urban life'. I can only wish that feeding the rest of my family was so simple—no cost, no coupons, no cooking and no washing up—I am etc.,

MARGARET PARDOE

#### Spinal Anaesthesia and Caesarean Section

SIR,—It is surprising to read in Dr N. Beattie's letter (Nov 13 p 877) that spinal anaesthesia is still being used for caesarean section. About eleven years ago there was a discussion in these columns (October to December, 1937) on this subject, and several fatalities were reported. In each case the patient collapsed shortly after the spinal injection. Professor Sebrecht in 1930 expressed the opinion (quoted by Dr Bagot Walters Nov 13 1937, p 995) that pregnant women must be given a reduced dose of spinal anaesthetic if serious accidents were to be avoided; he suggested that these patients were "rich sensible," but that is not the whole truth.

The explanation of this sudden and false collapse lies in the arrangement of the vasoconstrictor nerves supplying the abdominal and pelvic viscera; it is these nerves which if paralysed by spinal anaesthetic, cause the marked drop in blood pressure due to the deviation of circulating blood into the dilated "splanchnic pool." Vasoconstrictor nerves for the abdominal organs arise from the lower half of the dorsal region of the cord, and they are not greatly affected except by a high spinal anaesthetic. The pelvic viscera on the other hand are supplied by nerves from the first two lumbar segments and are paralysed in both high and low spinal anaesthesia, but the flooding of a non-gravid pelvis does not appreciably lower the general blood pressure. If, however, the uterus is at full term, even a low spinal anaesthetic may cause a massive vasodilatation of the largest and bloodiest organ in the body and the patient rapidly bleeds to death into the musculature of her own womb. The use of ephedrine will reduce the risk but the danger which is courted is so grave that spinal anaesthesia for caesarean section ought nowadays to be branded as malpractice. An unexpected death on the table is always a tragedy, but at this operation it is overwhelming, almost without equal in surgical practice—I am, etc.,

Hayle Cornwall

D. STANLEY-JONES

#### Classical Caesarean Section

SIR,—I was very much impressed by the remarks of Dr N. Beattie (Nov 13, p 877), who makes the vital point that care and technique can make even this much-abused operation safe. May I add a small consecutive list of 84 cases done at the Victoria Hospital, Deal, during the past twenty years to confirm his experience? Although two thirds of them were in the pre-sulphonamide penicillin era and include many cases of failed forceps and obstetric emergencies, there have been no maternal deaths and no ruptured uteri in later pregnancies. The series includes 5 caesareans on one patient and 4 on another and several cases of multiple normal labours in later pregnancies.

In all cases the uterus was sewn up with four layers of No. 4 catgut, the last two burying the suture line to prevent adhesions. An assistant was always present to squeeze the uterine arteries and prevent undue bleeding so that the temptation to make the operation dramatic should at all costs be resisted. Recent review of the case notes shows only two major complications. One case developed a gangrenous appendicitis on the 10th day (most of the others had a routine appendicectomy at the time) and the first case in the series where the dramatic temptation had not been resisted, came back with uterine adhesions and endometritis six months later and had a subtotal hysterectomy.

Probably the later cases have a good deal to thank her for, as one learns best from one's own mistakes.

Without holding any brief for a now outmoded operation I do feel that for many of the recorded bad results the surgeon may have only himself to blame. The same applies with greater force to some of the shocking figures published of recurrence after simple herniotomy. A possible explanation of these is the omission of adequate knot instruction in the training of potential surgeons. Many ruptured abdomens might be avoided if all candidates for a surgical Fellowship were required blindfolded to tie a reef knot behind their backs—I am, etc.,

Walmer Kent

JAMES S HALL

### Intra-abdominal Hydrocele

SIR—In this part of the world hydrocele is about the commonest surgical condition met with. In my nineteen years as a bush surgeon I have dealt with several hundreds of cases, so it was rather extraordinary that a few days after reading Dr A D Charters's letter (Sept 25 p 618) I should meet my first case of intra-abdominal hydrocele. The patient was a Hausa from the Wase area of Northern Nigeria. His hydrocele was moderately large by local standards, but after drawing off three pints of fluid by cannula and finding still more to come I realized the condition. A finger was easily passed up the inguinal canal into a large abdominal sac still containing fluid. Pressure on the lower abdomen rapidly emptied the sac of a further three pints of fluid. In this case the complication was easily dealt with for by moderate traction the abdominal sac was delivered into the scrotum. This supports the theory that the abdominal sac is formed by distension of a funiculo vaginal process—I am, etc.,

Pankshin N Nigeria

W McLELLAND

### Fowler's Position

SIR—The following objections have been made to the sitting-up of patients with peritonitis, particularly after perforation, and of patients after abdominal operations.

(1) The position causes wrinkling of the abdominal wall, and in fat patients 'cutting in' of deep sutures and tendency to 'gaping' of the wound.

(2) Crowding down of the intestines into the lower abdomen with impaction at the pelvic brim and consequent obstruction to the free onward passage of faeces.

(3) The patient is exhausted by the need constantly to restore him to the upright position after his frequent lapses into the supine position.

(4) The gas bubble in the peritoneal cavity rises to the top of the abdomen and reaches the subphrenic spaces. This causes the aspiration of liquid past the liver into the subphrenic spaces because the gas bubble contracts and expands in response to the variations in pressure transmitted to it by the diaphragm. In this way subphrenic abscess is rendered more likely.

(5) There is said to be a thin film of liquid between the diaphragm and the liver which maintains cohesion between the two. The gas bubble destroys this, and the liver is said thereafter to hang by its ligaments. This causes reflex diminution in movement of the diaphragm and diminished air entry into the lungs.

(6) The normal reciprocal antagonistic action between the downward thrust of the diaphragm and the returning pressure of the abdominal muscles goes to waste in compressing the bubble instead of being fully utilized for its proper purposes.

The foregoing may be valid criticisms of the upright position, but they are not valid criticisms of Fowler's position. On March 1 1900 G R Fowler read a paper to the Brooklyn Surgical Society in which he gave his views and described nine cases. No case was of perforated peptic ulcer. All except one were cases of perforated appendix with general peritonitis. Later (June, 1900) he described three more cases of general peritonitis due to perforated appendix. They were consecutive cases and all recovered. Fowler advised that the head of the bed should be raised 12–15 in (30–38 cm). In one case only was it raised 18 in (45 cm). He did not advocate the full upright position of the trunk. Fowler knew of the danger of phlebitis from the presence of the pillow behind the knees and recommended daily massage of the lower limbs to counteract that. Fowler's position was in contrast to 'Clarke's position,' in vogue thereto in which the foot of the bed was raised.

If Fowler's advice is correctly followed the objections disappear—the abdomen does not wrinkle, the viscera are not compressed, the patient does not slip down the gas bubble remains in contact with the anterior abdominal wall and does not rise to the top above the liver. It seems likely that Fowler's method has fallen into disrepute because it has been overdone—probably on the principle that you cannot have too much of a good thing. Fowler's back rest seems to have been devised by an assistant of G R Fowler, named R S Fowler, at a later date—I am, etc.,

### Traumatic Forequarter Amputation

SIR—Dr J D C Millar's description (Sept 18, p 559) of a traumatic forequarter amputation and his remark that a search of the literature had failed to reveal another case prompts me to record this case.

On April 25, 1947, a male Chinese railway workman aged 55 was brought to hospital in a state of shock and was seen by me. The history obtained was that the patient had been run over by a train four hours previously, being knocked unconscious and seriously injuring his left shoulder. There had been considerable haemorrhage.

On examination he was found to be semi-conscious, very pale with a feeble rapid pulse, and obviously shocked. There were abrasions over the left eyelids and face. A subconjunctival haemorrhage was present in the right eye and vision appeared impaired in both eyes. Eye movements and corneal and pupillary reflexes were normal. There was no bleeding from the ears, nose or throat.

Obliquely across the left side of the base of the neck and extending down and across the axilla the skin and subcutaneous tissues were split exposing torn fibres of the pectoral muscles, a fracture through the middle of the clavicle, the torn ends of the axillary vessels and brachial plexus, and the avulsed scapula with all its muscles. The scapula and head of the humerus were both badly fractured. A small piece of skin posteriorly was all that united the avulsed forequarter with the trunk.

There were diminished breath sounds and moist rales at the left base but no evidence of fracture of the ribs. He had also sustained a severe laceration of the index, middle, and ring fingers of his right hand, with exposure of the bones. No other injuries were evident.

Anti-shock measures were instituted, and when his condition had improved he was taken to the operating theatre and the forequarter removed by dividing the bridge of skin. The arm already showed rigor mortis. The torn muscles were trimmed, vessels and nerves ligated, and the wound closed with drainage, there being ample skin available. The drain was removed 24 hours later. The lacerations of the right hand were trimmed, sutured and dressed. A blood transfusion was given, and penicillin and sulphadiazine therapy instituted.

His subsequent course was smooth, a lumbar puncture revealing no blood in the CSF and an x-ray of the chest showing no fractured ribs. He complained of blurred vision and was found by Dr S C Liang to have some haemorrhage into the posterior chambers of both eyes. Primary union of his wounds was obtained, but the track of his drainage tube required curettage on May 21 before it finally healed. He was discharged on June 4.

I wish to thank Mr W R Welpy, consultant orthopaedic surgeon for help in the preparation of and permission to publish this case.

—I am, etc.,

### Animal Experiments

SIR—In the Harveian Oration (Oct 23, p 753) Dr F M R Walshe while emphasizing the first and simple order of experiment—clinical experiment—notes also the increasing use and value of animal experiment in the contemporary history of medicine. This trend is striking in much recent research and study. That animal experiment and the use of animals for scientific purposes such as the preparation of drugs, vaccines, sera, etc., are justifiable cannot be questioned and probably in this country the provisions of the Cruelty to Animals Act, under which vivisection is carried out, are properly observed. But it is a fact that on no occasion during the five years 1943–7 has an inspector under the Act given instructions that an animal which appeared to be suffering considerable pain should be killed at once (*Hansard* July 1, 1948 col 223).

That numbers of animals must have suffered considerable pain or misery does not seem in doubt from the nature of experiments described in the literature. To give one such example from the same issue of the *Journal* (p 752)—when referring to the assessment (in the U.S.A.) of tetraethylammonium compounds

by means of excision of the lower end of the tort in dogs, you state in your annotation, "In a control group nine out of ten animals died after one to seven days with cold, cyanosed, and paralysed limbs." I would suggest, Sir, that experiments involving animals in considerable pain, mutilation in which life is long preserved, or prolonged misery (such as food or water starvation) are unjustifiable and of doubtful value in the progress of clinical medicine—I am, etc.,

MICHAEL C. PLATTEN

### H 11 in Malignant Disease

SIR,—I should be grateful if you will permit me to reply briefly to the letter of Mr Fauset Welsh (Dec 4, p 997), as it refers to my patient whose history I recounted in a previous letter (Nov 13, p 876). Mr Fauset Welsh is perfectly correct in stating that this was the patient he kindly treated for me early this year and subsequently, but I had no intention of making the assumption, which he attributes to me, that here was a case of secondaries in the liver disappearing under H 11 therapy. In fact, I stated clearly in my letter that the palpable nodules in the liver were *thought* to be due to secondaries.

The surgeon under whose care the patient was originally admitted to hospital has since died, but in a letter to my partner at the time he wrote, "The abdomen was opened on March 22 and the liver was found to contain secondaries and so nothing beyond a colostomy was performed." Subsequently we found that the laparotomy was performed by a surgeon who has since changed his opinion, as stated by Mr Fauset Welsh. Surely, however, one is entitled to consider that the observations of the operator made at the operation are possibly of more value than his reminiscences after a lapse of two years. However, this is a matter of opinion, and I quite agree that the disappearance of liver secondaries has not been proved in this case. My sole object in writing to you about the cases I have treated with H 11 was to show that a negative attitude to H 11 likely to be engendered by the report of the committee of the Medical Research Council published in your issue of Oct 16 (p 701) and your leading article in the same issue (p 716) might not be correct and might result in a therapeutic agent being abandoned without fair trial. I hope and believe that the correspondence you have published will prevent this from occurring—I am, etc.,

Birmingham 17

H. JOSEPHS

### Dr Strickland Goodall

SIR—I have read with interest Professor John McMichael's Strickland Goodall Lecture (Nov 27, p 927). As one who was mainly responsible for instituting this memorial lectureship I should like to add a few words about Dr Strickland Goodall. He was one of the first to use small doses of digitalis in patients with failing heart long before the value of mercurial diuretics was recognized. I had the privilege of working with him for 15 years and had ample opportunity of appreciating his clinical acumen and the benefit patients derived from his treatment. Dr Strickland Goodall was one of the pioneers of modern cardiology and I shall be very sorry if his work is forgotten by later generations of cardiologists—I am, etc.,

London W 1

T. JENNER HOSKIN

### Colour Index Nomogram

SIR—I have read with interest Dr R. Elsdon-Dew's medical memorandum (May 24, 1947, p 723) in which he describes a slide rule for the ready determination of the colour index. He criticizes the nomogram devised for this purpose<sup>1</sup> as being less accurate at low cell counts. While this is theoretically true, the nomogram remains more than sufficiently accurate for all practical needs and has been in regular use for over two years at the hospitals with which I have been associated.

Contrariwise, it may be argued that a slide rule needs time and skill for its construction and, if manufactured, would be comparatively expensive. Messrs Hawksley & Sons Ltd, have made a colour index nomogram to my design which is priced at 2s 6d.

It has been asserted that the colour index is a conception that has outlived its usefulness.<sup>2,3</sup> While this may be the case, its use is retained by popular convention. In any event it is

the mean corpuscular haemoglobin content that is measured, whether this is expressed as an index or in micromicrograms, and purists will find the nomogram equally useful if the centre scale is calibrated in the latter units—I am, etc.,

### Clouding of Surgeons' Spectacles

SIR—Like Mr G. K. Rose (Dec 4, p 998) I was greatly troubled with steaming when I first took to wearing spectacles at operations. As this is so universal I feel that any method of overcoming this nuisance is well worth while airing. I run a piece of thick silver wire about 4½ in (11 cm) long through a fold stitched along the top of the mask. When in place, the wire is moulded to the shape of the letter V. The mask then covers the nose but does not come in contact with it. The method is simple, allowing the mask to be removed between operations without any further adjustments—I am, etc.

Hereford

R. WOOD POWER

### Safer Milk

SIR—Having read Dr W. A. Lethem's remarks (Dec 4, p 999) concerning remote places, such as in the Welsh mountains, I am prompted to write to you of my findings in the area of the practice in which I work, in the centre of which there is a dairyman who distributes pasteurized milk. In the Wareham area (of my practice) there are eight village schools. Of these five were being supplied with pasteurized milk, one with milk from T.T. cows and two with ordinary milk. In the Dorchester area there are three schools, one only of which received pasteurized milk as a rule, otherwise T.T., the other two received ordinary milk. In none of the non-pasteurized schools was the precaution of 'scalding' the milk being taken—I am, etc.,

Wimborne Dorset.

P. R. BOUCHER

### Medical Films

SIR—I should like to write in support of Mr Malcolm Donaldson's excellent letter (Nov 27, p 955) on this subject. The majority of medical films, and more especially those demonstrating surgical procedures, however technically excellent are valueless from the teaching aspect. Operations are the most difficult of all subjects but they seem to have a peculiar attraction for the film-maker, leading to a neglect of other subjects more amenable to cinematic treatment.

It would be well to consider the conditions necessary for the production of films of real teaching value. First, it must be determined exactly what procedure is to be demonstrated and whether in fact this can be done by the camera. In a film of operative technique each point to be brought forward must be individually considered and planned. It is not enough to say, "We will film this operation in its entirety." This will lead to a failure to make the essential teaching points and to the inclusion of irrelevant detail.

Secondly, the film must be made for a limited audience—limited not in numbers but in their knowledge and capabilities. It is impossible to obtain the precision necessary for teaching if it is attempted to appeal to both the expert and the beginner.

Thirdly, the amount of time and trouble involved in making a good film is far greater than most medical people realize. It is fantastic to think, as many do, that ten minutes of screen time can be successfully shot straight off in an operating theatre. This amount of screen time might easily in other circumstances involve several days shooting from a carefully prepared script. If the circumstances make this type of shooting unavoidable then planning and co-operation must be at the highest pitch of efficiency.

It is this co-operation between the medical producer and the film-maker that is the greatest factor in the production of a successful result. Unless the aims and methods are clearly understood and agreed upon the results will be vague and indefinite and leave no visual impression on the audience. Far better film lasting five minutes with the essentials driven home than twenty minutes of vague waffle. The time and trouble involved

in all this will be amply rewarded, for, although the audience is limited in scope their potential numbers on a nation-wide or international basis are very large indeed—I am, etc.,

The Photographic Department  
St Mary's Hospital Medical School  
London W 2

PETER N CARDEW

SIR—I was particularly interested to read Mr Malcolm Donaldson's letter (Nov 27, p 955), with which I agree entirely, as it raises several important points regarding the use of films in medical teaching. The true worth of this medium as an aid to teaching is at last beginning to be recognized. But, as with all new toys, films at present are being made and used in a haphazard and often uneconomical manner. To make a film, and particularly a good film is an expensive business. It is essential, therefore, particularly as public money is often involved that films made for this purpose should be designed for the present at least to reach the largest audiences possible.

This brings us at once to the question as to the type of film to be made. The film of an unusual operation or obscure physiological process has little or no wide value for teaching purposes. On the other hand, many aspects of hygiene and preventive and social medicine are eminently suitable for teaching by means of films—not only to medical students but also to postgraduates and ancillary public health personnel, health visitors, sanitary inspectors, etc. Again, many subjects such as 'inflammation', 'swellings', "signs and symptoms, and certain of the common infectious diseases and disorders might well make excellent films for the teaching of students during their clinical training.

Finally let us see that the films which are produced are good. When the film is being made it is not enough to have a good technical staff and an eminent medical expert, the man who is to use the film, the teacher, must play a large part. Only he can say exactly what is most needed. If the best use is to be made of this most valuable aid to medical teaching let us not forget 'First things first'—I am, etc.,

London WC 1

E GOODWIN RAWLINSON

### Medicine and Economic Survival

SIR—We hear much of the economic crisis, of the backwardness of British industry, of the ending of the sellers' market. If the country goes down we all go down, in peace as in war. Doctors working in industry, and the general public also, hear of the working parties which are intended to cut out the dead wood, help the Chancellor balance his Budget, and prepare for the day when Marshall aid ceases. I believe we are over thirty millions on the wrong side every month. If then there is this situation of urgency, if every aid to efficiency is so vital, why is it that the number of doctors working on these problems is so small and why are they so badly paid? It is impossible to believe that there is any sincerity in Government measures designed to improve our economic position while this situation obtains.

Many unskilled workers in industry are as well or even better paid than a professional man who is endeavouring, after years of study to improve their conditions. But when the crash comes blame will be attached to those who ostensibly failed to improve the technique of production, and it will not be particularly obvious that they were never given a chance. I refer in particular to those working for the MRC. In my opinion the situation calls for immediate action by the Chancellor, acting in agreement with the Minister of Health—I am, etc.,

Birmet Herts

G C PETHER

### POINTS FROM LETTERS

#### Rasher Bone in Anal Canal

Dr M NAUGHTEN (Clonmel, Co Tipperary) writes: Lieut J S Happel (Nov 20 p 919) gave an account of a partridge bone which, swallowed by a woman, was held up at the anal canal and I am prompted to mention a similar case. The victim was a male aged 47. He swallowed a rasher bone at breakfast. After suffering intense agony he was relieved of the bone at lunch time. Examination per rectum, difficult because of sphincter spasm, revealed a hard jagged object. It was about 2 in (5 cm) from the anus and was across the canal. It dropped into the axis of the bowel after some

fingering about, and was extracted later with the aid of dressing forceps. It was over 2 in long and  $\frac{1}{2}$  in (1.25 cm) wide at the broadest part. The patient had had teeth extracted some weeks previous to this experience. In his edentulous state he evidently was not acclimatized to the necessity for smaller bites. As in Lieut Happel's case, the differential diagnosis in the initial stage was difficult. The patient did not associate the swallowing of the bone with his intense anal pain and spasm. It was only towards the end that he recollected having momentary trouble in swallowing the bone. There was a history of vague ill health and of angina pectoris for a few years. The agonizing pain at first suggested some aberrant form of angina. When this was ruled out and a rectal examination done the presence of external piles suggested a strangulated internal pile. The bone itself even gave the impression of some sequestrum which had become detached and extended itself into the rectum. It is truly amazing what a length of bowel a large object can travel without causing much ado until the sphincter is reached.

#### The M'Naghten Rules

Dr THOMAS REES (Leigh on Sea, Essex) writes: I am shocked by Dr Clifford Allen's letter (Nov 27, p 955). May it not be that the prison doctor, besides being a general practitioner, is also a man? Being a man, he may also picture the mutilated little victim staring with uncomprehending terror into the face of a ravening beast as death mercifully clouds the dreadful scene. Let us by no means repeal the M'Naghten rules. Rather than these wild beasts should be sheltered behind a cloak of sentimentality, let the psychiatrists be excluded from such trials.

#### Breast-feeding

Dr I H J BOURNE (Hornchurch, Essex) writes: A point in breast-feeding which is generally overlooked and, in my opinion, is a clue to many problems is the period between the milk entering the baby's stomach and the nourishment entering the baby's blood stream. As in adults this interval can be one of continued hunger, that is if sufficient nourishment has been taken. The appetite normally disappears for one or both of two reasons. First, if the stomach is distended, and, secondly, if the blood sugar level has sufficiently risen. It follows that if a baby has had its calculated number of ounces of milk it may still cry with hunger for a period up to half an hour. After this time the blood is sufficiently enriched and the baby will sleep again. If the mother is uninstructed, and especially if she has no scales, she will be tempted to give more milk and overfeed the baby. This may overstretch the stomach and cause pain. Luckily the ritual of "bringing up the wind" for the baby gets most mothers over a period of crying, and the baby goes to sleep when the nourishment enters the blood stream. It is of course true that distension with swallowed air will terminate a baby's appetite and be the cause of pain after meals. I do not wish to suggest that bringing up the wind is not a helpful procedure in its own right.

#### Taking Children's Temperatures

Dr WINIFRED HALL (Northenden, Manchester) writes: I was very interested in the article by Professor Alan Moncrieff and Dr B J Hussey (Dec 4, p 972) on temperature recording in sick children. It seems to me that the resting pulse rate is a much more accurate guide to a child's state of health than a temperature taken at any point. I have so often found, particularly at the beginning and end of an illness, that the resting pulse is raised when the temperature is normal that I do not now regard a child as well unless the resting pulse rate is normal. If the pulse rather than the temperature were accepted for recording it would seem simple for a ward nurse to count the pulse when the child was asleep.

#### Early Rising after Operation

Mr K E H HALNAN (Cambridge) writes: I should like to express complete approval, from a patient's viewpoint, for your editorial "Early Rising after Operation" (Dec 11, p 1026). Your references to improvement of morale and avoidance of bed pan and bottle are particularly apposite. I have recently undergone a partial gastrectomy, after which I got out of bed on the third day and felt much steadier on my legs than I had done fifteen years ago when I got up more than ten days after a quite ordinary appendectomy. Condemnation of Fowler's position as a routine is also reinforced by the practical point that it increases many times one's difficulty in sleeping—also, being unable to move from an unaccustomed position, it becomes impossible to pull up the bed clothes to muffle the disturbing noise and lights that are still bound to occur in a general ward during the night. One minor additional suggestion (more applicable to medical wards) is that it should be recognized that an intragastric milk drip, etc., need not confine one to bed. Most patients are perfectly capable of disconnecting a Ryle's tube for a few minutes provided they are shown how and given a spigot to close the tube and a spring clip to shut off the milk drip. The screw clip controlling the speed of the drip need not be touched necessarily.

## Obituary

Dr ARCHIBALD DEANE died suddenly on Nov 8 at the age of 73. Although he retired from practice in 1946 he still continued to attend both the in-patient and out-patient clinical rounds of the Radcliffe Infirmary until the time of his death. From his early days as a practitioner his professional activities were wide and varied. A student at Aberdeen University and St Mary's Hospital, he graduated M.B., B.Ch. in 1902 and proceeded M.D. in 1910. After appointments as house surgeon at the Children's Hospital, Paddington, and the East Suffolk Hospital, and later as senior clinical assistant at the Brompton Hospital, he went into practice in Eastbourne. It was in 1912, not long after he settled there, that he first acted as assistant medical officer to the Princess Alice Memorial Hospital. In 1922 he was appointed a surgeon on the senior staff, and when the hospital became a teaching school for nurses and the post of physician was created he took over the duties of this office. Among his other activities he was police surgeon for many years. He was also chairman of the Eastbourne Branch of the British Medical Association in 1924-5 and a past-president of the Eastbourne Medical Society. To his colleagues in Eastbourne it was a matter of sincere regret when he decided in 1935 to leave the town and take up a less exacting practice in Abingdon. He left behind him a record of hard and skilful work for those under his care and the memory of one who hid behind a somewhat abrupt manner a kind and generous nature. From 1935 to his retirement in 1946 he was physician to Warren Hospital, Abingdon, and medical officer to Morris Motors. He died as he would have wished, able to the last to keep in active touch with his profession.—G D S

Dr EDWARD JOHN CROSS died on Nov 17 at his home in St Neots, Hunts, at the age of 83. Dr Cross was a student at St Thomas's Hospital and qualified in 1888. He took the Cambridge D.P.H. in 1893 and the M.D. of Durham University in 1906. He settled in St Neots soon after qualifying, in the first place as an assistant to Dr F. T. Good. When Dr Good died in 1894 Dr Cross took over the practice and continued there for just short of fifty years. He did not retire until December, 1943. He was medical officer of St Neots Urban and Rural Councils for many years and medical officer to the Post Office. Dr Cross served in the Middle East in the 1914-18 war and was in command of the Eastern Mounted Brigade Field Ambulance. He was twice invalided home, and in 1916 he took charge of the Citadel Hospital in Cairo. In the recent war Dr Cross undertook the usual air-raid and civil defence duties from 1939 until the end of the war in 1945. Dr Cross was one of the founders of the St Neots British Legion. He was the first chairman in 1922 and was later president of the branch. He was also county medical officer for the Red Cross and for many years president of the St Neots Conservative Association. Less than a year after his retirement Dr and Mrs Cross celebrated their golden wedding.

Dr WILLIAM REGINALD GROVE died at St Ives, Hunts, at the age of 79, on Nov 28. Dr Grove had been in general practice in St Ives for fifty-four years. After being a chorister at King's College, Cambridge, and a good rowing man at Sidney Sussex College, he went to Guy's Hospital, and would have done house appointments there had not his father's illness forced him to take over the family practice at St Ives. Acute observation of his patients and a keenness to absorb and try out new ideas in medicine were characteristic of him, but always with the belief that all the latest cure-alls have their day and vanish. Dr Grove made personal friends of his patients and knew their past history and domestic troubles. He always emphasized the fact that doctors have to deal with human beings, with troubles mental and physical and not with diseases. He took his M.D. whilst in busy general practice, writing his thesis on Graves' disease partly from observations made on more than one member of his own family. He was dogmatic and self-reliant both good qualities in a country doctor. He was a member of the Church of England Men's Society and for many years president of the Ely Branch. Dr Grove was always a keen member of the B.M.A., and served as president of the Cambridgeshire and Huntingdonshire Branch during the whole of the 1914-18 war. His hobby was photography, and he was a pioneer in colour and stereoscopic photography. He was also a pioneer in motor transport for doctors, starting in 1896 with a single-cylinder three-wheel car. He led a full and strenuous life and as he would have wished he died in harness.—C M S

Dr HUGH MUNDLE WILSON died at Linton, Cambs, on Nov 30 at the age of 63. Dr Wilson was born in Glasgow and educated at Glasgow High School and Glasgow University. He graduated M.B., Ch.B. in 1908. He spent two years in Liverpool, first at Stanley Hospital and later as a resident medical officer of the Liverpool Dispensary. In 1912 Dr Wilson went into general practice in Bridgeton, Glasgow, where his fine diagnostic skill and keen interest in his patients soon made him highly respected. During the first world war he served with the R.A.M.C. in India. On his return to this country he became the partner of Dr Wm Mortlock Palmer in Linton. To this widespread country practice he devoted all his energies. Naturally shy, reticent, and self-effacing, he nevertheless became the adviser and friend of all manner of people, and was the initiator and advocate of numerous schemes of public welfare. Dr Wilson was forced to retire from active practice on account of ill-health in 1945, and from then until three weeks before his death he acted as a medical officer for the Ministry of Pensions and his painstaking qualities and clinical skill were much appreciated at medical boards. He leaves a wife and two children.—N G C

Professor G. Grey Turner writes: In the early days of the 1914-18 war, when Cyril Cuff (Nov 27, p 960) was a sub-lieutenant in the R.N.V.R., he was in charge of a patrol vessel at the mouth of the Tyne, and it fell to the lot of this young medical student to undertake the responsible work of the examination of incoming craft. But most of his off-duty time and leave was spent at the Newcastle Royal Infirmary, and mostly in the operating theatres, for even in those early days he was intensely interested in surgery. Many a long morning he was at my elbow exhibiting that keenness which was characteristic of him throughout his career. In one of his resident posts just after qualifying he did quite a lot of major surgery, and with great success. Cuff was always fearless and that was exhibited in connexion with his own illness, for of course he knew the very ominous outlook in malignant larynx with involvement of the lymph nodes. When irradiation proved inadequate he came home to Newcastle from Cyprus and cheerfully submitted to the most radical surgery buoyed up by the hope that he might be able to fulfil his great desire for a return to his surgical work. That he did resume practice and his operating, if only for a short time, was a great tribute to his courage and determination. Those who remember him as the light-hearted lad buffeted about week after week in a small craft at the mouth of a busy river at a critical stage of our naval warfare will be saddened that he has not been spared to carry on his chosen work in the same spirit for a few more years.

Sir Ernest Graham-Little writes: Your well-informed and very full obituary of my old friend, J. H. Sequeira (Dec 11, p 1040), reinforced by the personal tributes from two of his pupils, deals more particularly with his very brilliant dermatological career. I would ask your permission to add a few comments on the remarkable Indian summer of his activities in a wholly new field which occupied the last twenty years of his life. Sequeira astonished his large circle of friends in London when, at the age of 62, he suddenly emigrated with his wife to Kenya, where, with the exception of two short visits to London, he remained until his death. During this period we corresponded frequently. He had been one of my original nominators for Parliamentary election in 1924 and he continued this support right to the end. His last letter to me from Nairobi is dated January, 1948 and he was able to say that he was still leading a very active and full life, notwithstanding the loss of the sight of one eye from glaucoma. He threw himself immediately into an investigation of native conditions, especially as regards their susceptibility to disease, and he embodied his researches in the memorable Chadwick Lecture of April, 1932, which he came to London to deliver. He shattered the legend so comforting to an indolent Colonial Office that the African native in his primitive state is a superlatively healthy person. Sequeira demonstrated with copious documentation that in fact the average individual native suffered from a simultaneous invasion of a number of separate infections to a degree which occasioned the comment that he might be described as 'a walking zoo'. Child mortality, the surest indication of the health of a community averaged, as he records 400 per 1,000 in the native reserves. The conditions of the native population which he described sixteen years ago would seem to have undergone little essential change. In an article in *The Times* of Dec 1 its medical correspondent reproduces the statement by the B.M.A. Branch Council for Kenya that the health situation is so perilous that it may cause "regional and continental disaster within a few decades and presses the urgent need for the closest investigation of this position.

## Medical Notes in Parliament

### Remuneration

SIR ERNEST GRAHAM-LITTLE asked the Minister of Health if he knew that under the present statutory limitations a medical practitioner's income could not exceed £3 600 per annum gross whereas that of a dental practitioner could reach £4 800 per annum gross, and if in view of the fact that the period of professional training for the qualifying diploma in medicine was fifty-seven months, while the period of training for the dental qualifying diploma was forty-eight months he would review the position, which caused dissatisfaction among medical practitioners.

MR BEVAN answered on Dec 15 that he could not accept many of the implications in this question, but was about to review the present scale of dental fees in consultation with the profession.

### Artificial Insemination

SIR HARTLEY SHAWCROSS declared on Dec 13 that difficult questions had arisen in regard to the legitimacy of a child born during wedlock in a case in which cohabitation existed at the time of conception but did not take place after the marriage. Further difficult questions had arisen where a child was conceived either by means of artificial insemination or in spite of the fact that there had been no complete intercourse. Such cases were very exceptional. He said the Lord Chancellor doubted whether special legislation was desirable, but the matter was being kept under review.

**Certificates**—SIR JOHN MELLOR on Dec 13 asked whether Mr Bevan would amend the National Health Service Regulations to reduce the administrative work of doctors and enable them to devote a larger proportion of their time to treatment. Mr J. EDWARDS replied that Mr Bevan was always ready to consider any specific suggestions to that end, so long as the intentions of the Act were safeguarded.

**Rations for Diabetics**—Persons who produce a medical certificate indicating that they suffer from diabetes retain all the ordinary rations except sugar. In addition they are allowed 12 oz of butter and margarine, 12 oz of cheese, and two rations of meat a week. Where the medical certificate classes a diabetic patient as in need of a special supply of milk, a priority allowance of 7 pints a week is also granted.

**Aganized Bread**—MR STRACHEY states that nitrogen trichloride is still used in the manufacture of wheat flour. A scientific committee including Sir Edward Mellanby and Sir Wilson Jameson was reviewing its use. Mr Strachey will be guided by their conclusions. He added that Sir Edward Mellanby had done the most recent work on the question.

## Medico-Legal

### CRUELTY OF AN INVALID

[FROM OUR MEDICO LEGAL CORRESPONDENT]

The wife of an officer serving in India was a chronic invalid. Over a period of years she made very exacting demands on him. He had to bathe her and dress her and she systematically for nights on end prevented him from sleeping by demanding that he should read to her. If he showed signs of going to sleep she stripped the clothes from his bed, moved furniture about the room and switched on the lights. Ultimately his health broke down. When the couple returned home he left her and petitioned for divorce on the ground of cruelty. Mr Justice Finnemore dismissed the petition holding that her conduct was not cruelty in a legal sense as it was not deliberate, malignant or intended. The Court of Appeal however gave the husband his divorce holding that the judge was wrong in law.<sup>1</sup>

Lord Justice Tucker admitted that the state of health of the parties was a relevant matter to be taken into consideration, and that it was the duty of each spouse to care for and show forbearance towards the other in illness. On the other hand if certain conduct was legal cruelty it was not necessary

to inquire into the motives behind it. There was no need to prove malignity. Lord Justice Evershed added that some limit must be set to the obligation of a spouse to take the other in sickness and in health.

The wife's conduct had seriously injured the husband's health and rendered it impossible for him to continue to live with her, and this constituted cruelty. On the other hand Mr Justice Hodson, who has had long experience of the divorce court, disagreed with the opinion of the two Lords Justices on the ground that the judge at the trial did not find cruelty as a fact. He did not agree that the husband was at any time acting under compulsion, he had written to his wife during the events complained of asking her to join him, and he only alleged cruelty many years after the events because his wife would not divorce him for desertion. Cruelty (as Lord Justice Asquith said recently) must exceed in gravity such behaviour, vexatious and trying though it might be as every spouse bargained to endure when accepting the other for better or for worse. The ordinary wear and tear of conjugal life did not in itself suffice. He therefore was for disallowing the appeal.

The acceptance by the husband of the conduct he complained of later was of course, a strong point against him and unless the court had taken the view that he had to a large extent acted under compulsion it would probably have dismissed his appeal. This case also emphasized the distinction between violent and disorderly affections of the mind, as a judge once put it and disease of the mind sufficient to prevent the spouse from appreciating the nature and quality of her acts. The distinction may be easier for a lawyer than for a psychiatrist to make but the case of *Asle v Asle* (1939) clearly settles that if insanity is proved a petition on the ground of cruelty must fail.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

Matthew Bennett, M.D., D.M.R., Assistant Director of the Radio therapeutic Centre, has been recognized as a Lecturer in the Faculty of Medicine.

### UNIVERSITY OF EDINBURGH

Walter Mercer, M.B., F.R.C.S. Ed., has been appointed as the first incumbent of the recently established Chair of Orthopaedic Surgery in the University. Mr Mercer will hold the appointment conjointly with the post of Director of Orthopaedics for the South Eastern Region of Scotland to which office he has been appointed by the Scottish South Eastern Regional Hospital Board. Part of Mr Mercer's work in these complementary posts will be the organization of undergraduate and postgraduate instruction with a view to the establishment of an Edinburgh School of Orthopaedics.

### UNIVERSITY OF LONDON

The Governing Body of the British Postgraduate Medical Federation on behalf of the University of London have appointed Mr L. E. C. Norbury to be Regional Adviser in Postgraduate Medical Education for the North West Metropolitan Hospital Region.

Mr J. B. Hunier has been appointed a member of the Committee on Higher Education in the Colonies for the remainder of the session 1948-9 and as the second representative of the University on the Inter University Council for Higher Education in the Colonies for the period ending July 31, 1953.

Dr W. F. Harper has resigned the post of Reader in Anatomy at London Hospital Medical College from a date between Jan 1 and April 1, 1949.

A detailed scheme of examination for the first examination for medical degrees at the University College of the West Indies has been approved. The examination is to be held for the first time in June, 1949.

### FACULTY OF RADIOLOGISTS

The following candidates satisfied the Fellowship Board at the recent examination for the Fellowship of the Faculty of Radiologists: **Radiodiagnosis**—E. P. Allen, M.B. Ch.B. J. H. Middlemiss, M.D., **Radiotherapy**—G. W. Boden, M.R.C.S. M.R.C.P., W. M. Court Brown, M.B., Ch.B. O. B. Millar, M.D.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Dec 4

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	33	2	19	1	1	46	4	21	2	—
Diphtheria Deaths	131	10	42	6	4	205	21	38	28	8

Deaths (0-1 year) Infant mortality rate (per 1 000 live births)	341	36	35	17	11	373	49	66	27	19
Deaths (excluding still births) Annual death rate (per 1 000 persons living)	5 967	1019	698	198	119	5 563	861	722	205	155
Live births Annual rate per 1 000 persons living	7 607	1107	913	436	250	7 975	1327	962	304	212
Stillbirths Rate per 1 000 total births (including stillborn)	178	20	38	—	—	210	24	29	—	—

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only

† Deaths from measles and scarlet fever for England and Wales London (administrative county) will no longer be published

‡ Includes primary form for England and Wales London (administrative county) and Northern Ireland

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales London (administrative county) are combined

|| Includes puerperal fever for England and Wales and Eire

## EPIDEMIOLOGICAL NOTES

## Discussion of Table

In England and Wales there was an increase of 181 in the notifications of acute pneumonia and a decrease of 185 in the notifications of whooping-cough

Notifications of scarlet fever were 17 fewer than in the preceding week there was an increase of 34 in Yorkshire West Riding Although the total for the whole country only showed an increase of 15, there were large fluctuations in the incidence of measles increases in Durham 87, Yorkshire West Riding 52, Warwickshire 47, Yorkshire North Riding 43 and Gloucestershire 41, with decreases in Lincolnshire 105 Lancashire 63 and Derbyshire 58 The largest decreases in the notifications of whooping-cough were Lancashire 39 and Essex 30 and the largest rise was Yorkshire West Riding 55 The chief feature of the returns for diphtheria was a fall of 15 in Lancashire An increased incidence of acute pneumonia was noted throughout the country

The largest notifications of dysentery were London 10 and Lancashire 9 The largest returns of poliomyelitis were Southampton 5, Lancashire 5, Yorkshire West Riding 5, and Sussex 4 In Northumberland, Newcastle-upon-Tyne CB, 4 cases of cerebrospinal fever were notified

In Scotland the chief feature of the returns was a rise of 94 in the notifications of acute primary pneumonia Increases were recorded in the incidence of scarlet fever 13 and whooping cough 12, and there was a decrease of 32 in the notifications of measles In Glasgow the notifications of diphtheria rose from 14 to 21

In Eire an increase of 37 occurred in the notifications of measles and a rise of 29 in the notifications of scarlet fever A rise in the incidence of scarlet fever was general throughout the country An outbreak of measles, resulting in 29 notifications occurred in the rural district of Laoighis county

In Northern Ireland there was very little change in the trends of infectious diseases

## Week Ending December 11

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1 410 whooping-cough 2,522, diphtheria 144 measles 10 094, acute pneumonia 1 027, cerebrospinal fever 39 acute poliomyelitis 35, dysentery 69 paratyphoid 3, and typhoid 4

## Medical News

## Help for Chronic Sick

The Duke of Gloucester, presiding at a meeting of the General Council of King Edward's Hospital Fund for London on Dec 14 referred to changes in the future work and organization of the Fund It seems clear that, besides helping the relatively few hospitals disclaimed by the Minister of Health, we may be able to make a contribution to one of the most pressing problems of the day—namely, the need of homes for those who do not require to be kept in hospital The powers of the King's Fund do not extend to helping the aged as such—that we must leave to our friends of the Nuffield Foundation But there are many people in hospitals mostly over 60 years of age, who need not stay there but who do need some degree of nursing care and medical supervision It is all but impossible to secure admission for these people to any other institution, but they are taking up beds which ought to be filled by the acute sick He announced that the Distribution Committee would be glad to help voluntary bodies with substantial grants He also said that they planned to establish at St Pancras Hospital a training centre for hospital catering Since 1943 the Fund had been deeply interested in hospital catering and had been instrumental in effecting improvements The old regime of one cooked meal a day was a thing of the past But the whole movement was held up and indeed in danger of slipping backwards for lack of properly trained caterers and other personnel They intended to have at St Pancras a model kitchen, and room for various subsidiary and educational activities

## Russian Discoveries

The State Medical Library in Moscow, claimed to be the largest of its kind in Europe is holding an exhibition of medical literature according to a Moscow Radio report The main section of the exhibition is called "The Superiority of Russian Medicine" and discloses several Russian medical discoveries One book on show, for example, deals with the life of Nikolai Pirogov, the eminent Russian surgeon of last century, and claims that he was the first man

to use ether as an anaesthetic, in 1847. In the West the American dentist Morton is generally recognized as the first to have used it as an anaesthetic, in 1846. Pirogov is also named as the inventor of the plaster cast for fractures, and P. Pirogov was the father of modern field surgery, claims the report. Another monograph at the exhibition names Yanovich Chayinsky as the inventor of an original method of skin grafting in 1870. Years later, says the report, a U.S. scientist announced this as his own discovery. The report also claims that the discovery of insulin in the treatment of diabetes was wrongly attributed to Sir Frederick Banting. It was really discovered by Professor Sobolev, a Russian scientist. (*British United Press*)

#### Recognitions for Gallantry

The *London Gazette* has announced the appointment as MBE (Civil Division) of EDMUND MONK HAMILTON, M.B., B.Ch., B.A.O., ship surgeon, m.v. *Reina del Pacifico*, Pacific Steam Navigation Company (Bangor, Co. Down) and the award of the BEM (Civil Division) to Messrs S. BLAIR, R. G. CROTHERS, and F. WATT. The citation reads as follows:

While the m.v. *Reina del Pacifico* was undergoing sea trials a series of explosions occurred in the engine room as a result of which 28 persons lost their lives and 23 were injured. Conditions in the engine room immediately after the explosions were chaotic. All lights were extinguished and access was very difficult owing to smashed ladders, loose floor plates, and the obstruction offered by displaced crank-case doors. A number of fires broke out and escaping oil caused grave risks of further explosions or more serious fires. The ship surgeon Mr Hamilton immediately went to the engine room. The stairway to the main motor room was wrecked and despite the fact that the engine room was in complete darkness full of smoke and that fires had started he jumped in and gave first aid assistance to save life and ease the sufferings of those who had been badly injured. These services were rendered under exceptionally difficult and dangerous conditions and for three hours he was the only medical man on board. Blair Crotthers and Watt although fully aware of the danger did not hesitate to enter the wrecked engine room and showed courage and coolness in the work of rescue and in relieving the sufferings of their comrades.

#### Medical Golf

The Annual General Meeting of the Medical Golfing Society was held on Dec 9. Dr D. G. Halsted was elected president and Dr C. Carran Brown captain for the ensuing year.

#### Wills

Dr Charles Samson Thomson, late medical superintendent officer of health in Belfast, left £4,915. Dr Thomas Browne Bearder, of Ilkley, Yorks, left £11,993. Dr George Baynton Forge, of Handley, Dorset, £9,165. Dr James Ironside Hutcheson, of Edinburgh, £12,168. and Dr Eric Avery Gordon Goldie, of Richmond, £14,071.

### COMING EVENTS

#### British Association of Physical Medicine

A short course of lectures on the various aspects of physical medicine has been arranged on Tuesdays and Thursdays from Jan 4 to Feb 10, 1949, inclusive, at 5 p.m. The lectures will be suitable for candidates preparing for Part II of the Diploma in Physical Medicine. Further details can be obtained from the honorary secretary, British Association of Physical Medicine, 45, Lincoln's Inn Fields, London W.C.2.

#### Congress of Obstetrics and Gynaecology

The 12th British Congress of Obstetrics and Gynaecology will be held at Friends Meeting House, Euston Road, London N.W.1, on July 6-8, 1949, under the presidency of Sir Eardley Holland. The programme is as follows: *Wednesday July 6* 10 a.m. The Congress will be declared open by the Minister of Health. Modern Caesarean Section, introduced by Mr C. McIntosh Marshall (Liverpool) 2 p.m. (1) Endometriosis by Dr Joe Meigs (Boston, Mass.), (2) The Methods of Assay and Clinical Significance of Pregnenediol in the Urine introduced by Professor C. F. Marran (Edinburgh) and Dr G. I. M. Swyer (London) 8.45 p.m. Reception by the President and Council of the Royal College of Obstetricians and Gynaecologists at the University of London, Bloomsbury, W.C.1. *Thursday July 7* 10 a.m. Essential Hypertension in Pregnancy, introduced by Professor George W. Pickering (London) and Professor F. J. Browne (London) 2 p.m. (1) The Management of Pregnancy in Diabetes introduced by Mr John H. Peel (London) and Dr G. Douglas Matthew (Edinburgh) (2) Hernia of Pouch of Douglas, introduced by Mr Charles D. Read (London) 8-10.30 p.m. Reception by the President of the Congress at the Zoological Gardens, by courtesy of the Council of the Zoological Society of London. *Friday July 8*—10 a.m. 'Modern Concepts in Diagnosis, Treatment and Prognosis of Carcinoma of the Uterus' (1) The Diagnosis by Vaginal Smear by Dr J. E. Ayre (Montreal) (2) Precancerous Cellular Changes in Carcinoma of the Cervix, by Professor Gilbert I. Strachan (Cardiff) (3) 'Prognosis based on Biopsies' by Mr A. Glucksmann (Cambridge) (4) The Operation of Pelvic Exenteration by Dr Joe Meigs (Boston, Mass.) A discussion will follow each paper 2 p.m. Discussion on Maternal

Mortality, introduced by Sir William Gilliat (London) 7.45 p.m. Congress banquet in Guildhall. Those who hope to attend should apply as soon as possible to Mr A. J. Wrigley, Hon. Sec., 58, Queen Anne Street (Royal College of Obstetricians and Gynaecologists), London, W.1.

### SOCIETIES AND LECTURES

#### Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Dec 28, 5 p.m. *Histopathology of the Skin* by Dr I. Muende

INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street, London, W.C. Dec 28 11 a.m. *Film and Cultural Diagnosis of Gonorrhoea* by Dr R. Thomson

#### Wednesday

INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street, London, W.C., Dec 29 11 a.m. *The Complement Fixation Test in the Diagnosis of Gonorrhoea* by Dr R. Thomson

#### Thursday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Dec 30, 5 p.m. *Affections of the Lips and Mucous Membranes* by Dr Brian Russell

INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street, London, W.C., Dec 30 11 a.m. *Local Complications of Gonorrhoea in the Male* by Dr A. H. Harkness

#### Friday

MAIDA VALE HOSPITAL MEDICAL SCHOOL, Maida Vale, London, W.—Dec 31, 5 p.m. Case demonstration by Mr H. E. Hobbs

### APPOINTMENTS

COLLINS, F. M. M.Chir. F.R.C.S. Deputy Chief Medical Officer, Ministry of National Insurance

CRABB, JOHN, M.R.C.S. L.R.C.P. Port Medical Officer of Health, Hartlepool, Port Health Authority

MORRISON, J. O.B.E. M.C. M.D. D.P.H. Medical Superintendent for Aberdeen Special Hospitals

NORTHAMPTONSHIRE COUNTY COUNCIL.—District Medical Officers of Health and Assistant County Medical Officers of Health: W. Aitchison, M.B., Ch.B., D.P.H.; P. X. Birmingham, M.B., B.Ch., D.P.H.; A. Lucas, L.R.C.P.S. Ed., D.P.H. Assistant County Medical Officer of Health: Margaret M. F. Robinson, M.D., D.P.H.

OVEN, EVELYN, D. M.B., B.S., D.P.H. Whole time Medical Officer of Health, Carlisle Urban District Council and Assistant County Medical Officer

RIGBY, J. P. V. B.M., B.Ch. Chest Physician, Deptford Area, London S.E.

WEAVER, ROBERT, M.B., Ch.B., D.P.H. Medical Officer for Eastern District of Flintshire

### BIRTHS, MARRIAGES, AND DEATHS

#### BIRTHS

Bennett.—On Sept. 19, 1948, at Melbourne, Australia, to Christine (née Hudson of Cambridge) wife of Dr J. W. Bennett a son—David John.

Harvey.—On Dec. 8, 1948, at Hove, to Betty (née Woodward) the wife of Dr N. W. A. Harvey, twin sons.

#### MARRIAGE

Stowers-Alabaster.—On Dec. 10, 1948, at Haslemere, John M. Stowers, M.R.C.P., to Mary Alabaster, M.B., B.S.

#### DEATHS

Alford.—On Dec. 11, 1948, at Tyndale, Weston-super-Mare, Herbert Thomas Marmaduke Alford, M.R.C.S., L.R.C.P., aged 75.

Burres.—On Dec. 13, 1948, at Druid's Mead, Stoke Bishop, Bristol, Richard Burgess, M.R.C.S., L.R.C.P.

Cole.—On Dec. 9, 1948, at Seaford, Sussex, George Cole, M.R.C.S., L.R.C.P.

Dickson.—On Dec. 11, 1948, Jack Edgar Dickson, M.B., B.S., of 5 Grange Road, Bushey, Herts.

Frain.—Recently at Bailey, Yorkshire, William John Frain, M.B., Ch.B., D.P.H., aged 46.

Green.—On Dec. 13, 1948, at The Limes, Lakenheath, Suffolk, Hugh Frederick Green, M.B., C.M.E.d., aged 80.

Jones.—Recently W. J. Bennett Jones, M.D., Ed. of Liverpool.

Leslie.—Recently at Birmingham, Peter Leslie, M.B., Ch.B., Aberd.

Milstone.—On Dec. 9, 1948, at Guildford House, Chertsey, Surrey, Harry Blunt Milstone, M.B., B.Ch., aged 78.

Murphy.—Recently Richard Murphy, M.R.C.S., L.R.C.P., of 3 Halifax Road, Grenoside, Sheffield, aged 40.

Oliphant.—On Dec. 11, 1948, at Rydens, Bothenhampton, Bridport, Dorset, Frank Binfield Oliphant, M.B., C.M.E.d., aged 77.

Phillips.—On Dec. 4, 1948, at The Park House, Port Talbot, Glam., Evan William Monker Hubert Phillips, M.D., M.Ch., F.R.C.S. Ed., J.P.

Robertson.—On Dec. 14, 1948, at Radcliffe Infirmary, Oxford, William John Robertson, M.R.C.S., L.R.C.P., aged 85.

Stanton.—On Dec. 8, 1948, at Leeds as the result of an accident, Frederick Ritchie Stanton, M.B., Ch.B., Ed.

Smalley.—On Dec. 11, 1948, at Torcross, Kingsbridge, Devon, James Smalley, M.B.

Wells.—On Dec. 6, 1948, at Duncan, Vancouver Island, B.C., Canada, Albert Primrose Wells, L.R.C.P.S. Ed. and L.M., aged 94.

## Alert... AND FREE FROM PAIN

When the burden of pain proves too heavy,  
mental outlook becomes distorted. In such a case  
the drug of choice is Physeptone<sup>1</sup> which gives  
satisfactory analgesia while leaving the mind clear

### 'PHYSEPTONE'

di 2 DIMETHYLAMINO-4,4-DIPHENYLHEPTANE 5 ONE HYDROCHLORIDE

THE NEW ANALGESIC

## K-Y LUBRICATING JELLY

FOR SURGICAL INSTRUMENTS  
FOR DIGITAL EXAMINATIONS  
FOR ELECTROTHERAPY APPARATUS

This jelly is non-greasy, water soluble. It does not stain clothing or hands, nor does it irritate the most sensitive surfaces. Surgeons find it most useful for lubricating catheters and cystoscopes. In electrotherapy K-Y, being non-greasy, does not interfere with the current when applied to glass and metal electrodes. Send for sample and prices.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Infra-red Photography

**Q**—Infra red photography is sometimes used to reveal dilated subcutaneous vessels—for example in cirrhosis of the liver. Where can details of the theoretical principles and technical processes be found?

**A**—The essential feature is the ability of a suitably sensitized photographic plate to record wavelengths outside the visible spectrum, both ultra-violet and infra-red. Emulsions can be sensitized as far as 13,000 Å, but the most generally useful infra-red plates respond from 7,000 to 9,000 Å. These radiations are less easily scattered than visible light (hence the long range landscape photographs published before the war) and therefore they can penetrate, among other things, the superficial layers of the skin. The clinical applications are limited but important. Superficial veins are clearly seen in cirrhosis and other conditions and also in the lactating breast. The

fundus oculi may be photographed even when the cornea is opaque. Skin lesions become visible through quite thick crusts and scabs, this may be valuable in the control of healing in lupus. The lesions in sections of silicotic lung are very clearly revealed by infra-red photography, whereas on panchromatic stock they are masked by the predominantly dark lung tissue.

The practical handling of the material is described in the manufacturer's data sheets and is not essentially difficult. The theory is well covered, with a good bibliography in *Photography by Infra-red* by Walter Clark (Chapman and Hall, 1946). The two pictures here reproduced—from a case of venous obstruction in mediastinal Hodgkin's disease—show the kind of result that may be obtained with infra-red photography. In Fig. A a local telangiectasis is seen over the sternum, in Fig. B the veins in the superficial fascia, dilated as collaterals, are demonstrated. The details are as follows: (A) Panchromatic emulsion, sensitive to 6,700 Å, 1/10 second at f/18, no filter. (B) Infra red emulsion, sensitive to 8,800 Å, 1/2 second at f/22. Wratten filter 88A. In both cases identical tungsten lighting was used.

### Kyphosis

**Q**—Would physiotherapy or any planned course of exercises rectify a mild kyphosis? The patient is a tall slim young man of 22 who attributes the deformity to bad posture associated with dyspnoea (asthmatic) during adolescence. He is now in excellent health.

**A**—The degree of 'straightening up' which can be expected is dependent to some extent on whether the kyphosis is purely postural or whether there is in addition some underlying condition such as Scheuermann's osteochondritis. This

could be determined by radiological examination. In either case a planned course of exercises, designed to build up the tone and power of the posterior spinal muscles, would be beneficial. But if there is some structural change of the dorsal vertebral bodies improvement is unlikely to progress to the point of complete correction of the deformity. It should be emphasized that the exercises must be carried out in an intensive manner over a prolonged period and must be practised frequently at home as well as in the physiotherapy department.

### Human and Bovine Tuberculosis

**Q**—Is pulmonary tuberculosis in the human ever caused by the bovine organism? Conversely is there any evidence that infection has been transmitted to the cow by a man suffering from pulmonary tuberculosis? If so is it inadvisable for a patient with known pulmonary tuberculosis to milk cows in a T.T. herd?

**A**—Pulmonary tuberculosis in the human can be caused by the bovine type of tubercle bacillus. A considerable number of cases have been reported by Sir William Savage, A. S. Griffith, and P. W. Edwards. In 1933 of all pulmonary cases examined the proportion of bovine type was 0.8% in England and 3.8% in Scotland. It is probable that further typing of bacilli found in sputum will reveal that pulmonary tuberculosis of bovine origin is not so infrequent as it was once thought to be.

The human type of tubercle bacillus can cause very mild infection in cattle, but it rarely gives rise to symptoms. The infected animal reacts to tuberculin but the sensitivity is often transient. Should a person working in contact with cattle suffer from pulmonary tuberculosis due to the bovine type of bacillus it is possible for the cattle to become infected from that source and develop active lesions. It is certainly inadvisable, and in fact can be illegal under the Milk and Dairies Order 1926 No. 821 (Ministry of Health and Ministry of Agriculture and Fisheries), for a patient with known active tuberculosis to milk cows in a T.T. herd, primarily because of the danger of infecting the milk. If the patient suffers from bovine tuberculosis there is the added risk of the cattle becoming infected and developing the disease.

### Taenia Saginata

**Q**—What is the accepted treatment for *Taenia saginata* infection? I would appreciate a detailed description, as I have several persistent cases.

**A**—Preliminary starvation for forty-eight hours, with a daily saline purge, is important. Following this on the third morning give, for adults, freshly prepared oleoresin of aspidium 0.6 to 1.2 ml in gelatin capsules, one capsule every half-hour for three doses. Follow in half an hour with a full dose of sodium or magnesium sulphate. Examine all stools until the head is found. Successful treatment may necessitate the introduction of the drug by duodenal intubation. In case of failure the treatment should not be repeated until a month or six weeks later. It is probable that neither this nor any other drug used for the treatment of intestinal cestode infections is capable of killing the parasite *in situ*. Such drugs appear to act by temporarily anaesthetizing, paralyzing or irritating the worms thus causing them to relax their hold on the gut wall. This failure to kill the parasite explains the importance of purgation after administering the drug and the need for subsequently searching the patient's faeces for the head of the tapeworm in order to establish the success or failure of the treatment.

### Suprarenal Extract and Obesity

**Q**—I should be glad of any information regarding the use of suprarenal gland for reducing obesity, especially in women at the menopause, also the dose and contraindications to its use in such cases.

**A**—There is no evidence whatsoever that extracts of the suprarenal gland or synthetic adrenal products, have any effect on adiposity although the latter have often been prescribed without rationale and without success. If anything the available adrenal products would tend to increase weight rather than diminish it, and in some cases to increase the water-salt retention that is sometimes associated with adiposity.

## Measles Prophylaxis

## Q—Is there any reliable prophylactic against measles?

A—There is as yet no prophylactic vaccine which can be used to give children an active immunity against measles. Normal adult serum may be used to modify an attack, and in this way the child obtains immunity to further infection without suffering any ill effects from the measles. In young children under 2 years of age convalescent measles serum or concentrated globulin fractions may be used to protect completely against infection but such protection being of a passive nature, lasts only for two or three weeks. Normal adult serum is obtainable through the Public Health Laboratory Service. The supply of convalescent serum is usually limited and localized and the small amount of concentrated globulin fractions prepared in this country is at present being utilized in controlled trials to test its efficiency.

## Reiter's Disease

Q—A patient recently had Reiter's disease with the usual arthritis conjunctivitis and urethritis. He was treated by sulphonamides and NAB unavaciously and is now quite well. He is however worried over the dubious aetiology of his complaint and the fear of infecting his wife or future children. Are there any known facts of aetiology, treatment and infectivity in relation to marital relationship and future children?

A—There are one or two rare examples where Reiter's disease has occurred in a married couple and it has been suggested that the disease has been transmitted maritally. There is no evidence to suggest that the infection is transmitted from the parents to the children. The view that Reiter's disease is due to pleuropneumonia-like organisms is now gaining ground. To relieve his mind the patient should be examined to see that pleuropneumonia-like organisms are not present in the urethra. Streptomycin appears to act as a specific in Reiter's disease.

## Sea sickness

Q—A boy of 5 subject to severe attacks of cyclic vomiting is going to Australia. Attacks have occurred after long motor runs, yachting or nervous excitement and have frequently resulted in alarming collapse. Phenobarbitone seems to have prevented car or train sickness. What prophylactic measures are advised in case of bad weather at sea?

A—There seems to be a slight confusion of terminology in this question. Cyclic vomiting is surely a periodic phenomenon often cryptic in origin, but frequently tracked down essentially to recurrent infection in the type of nervous, excitable child who easily vomits. Presumably this is not meant in the question, since definite aetiological factors are mentioned. The problem posed is what can be done to prevent serious effects from sea-sickness in a presumably susceptible child. Sedatives should certainly be used and phenobarbitone is mentioned as effective in this small patient. The fluid intake should be kept at a high level, preferably before rough weather is encountered by means of sweetened fruit drinks. Rich fatty foods should be kept down to this country's present standards. Sweets, sweet biscuits and the like should be used freely to keep the liver well stocked with glycogen. The experience of the ship's doctor and nurse (if available) should be drawn upon at an early stage of the voyage so that the child has confidence in them should attention become necessary. The advantages of a low-pressure rectal drip might be remembered if dehydration should become serious.

## NOTES AND COMMENTS

**Sweating Hands**—Dr SAMUEL LOWY (London, W) writes in reply to a question it is suggested ("Any Questions?" Nov 27, p 967) that excessive sweating particularly affecting the hands in a 24 year old patient who suffered from this complaint all his life "is almost certainly emotional and may have a psychological cause amenable to psychiatric investigation and treatment. I should be glad to know the source of this encouraging statement. Certainly it is not in accordance with my own experience as well as that of my fellow psychiatrists engaged in the therapy of psychosomatic manifestations. I have tried it frequently during the early period of my career, and I can remember no case of palmar sweating existing from early childhood, or even from early adolescence, as the only nervous symptom yielding to hypnotic or analytic psychotherapy. Cases of hyperhidrosis may improve spontaneously later in life in the thirties. Sullivan and Bereston (*Amer J Psychiat* 1946, 103, 42), discussing psychogenic urticaria pruritus, and hyperhidrosis think that the prognosis for military service is poor even on limited duty. They recognize the significance of predisposition, so prominent indeed in the vast majority of cases. On the other hand Gutheil in his *Psychotherapie des praktischen Arztes* (1934 Leipzig) takes a rather optimistic view in not too severe cases, though he does not indicate the type of patients he has in mind. I myself have attained success only in cases where the condition developed after adolescence and was associated with other symptoms fit for analytical therapy.

**Phosphaturia**—Dr L. DUNN (Hull) writes. The answer to the question, "What is the best treatment for phosphaturia?" ("Any Questions?" Dec 4, p 1006) misses the main point. It does not deal with phosphaturia but with the physiological excretion of phosphates. Phosphaturia is a well known abnormality in which the kidneys do not excrete the normal quantity of calcium (about 0.2-0.4 g CaO in 24 hours) but amounts of about 0.4 g up to 0.9 g CaO in the form of insoluble  $\text{Ca}_3(\text{PO}_4)_2$  instead of the soluble calcium phosphates. The phosphaturic urine is alkaline and turbid. On the other hand urine can be alkaline and turbid due to lack of acid, the content of calcium being normal. In this case insoluble  $\text{Ca}_3(\text{PO}_4)_2$  salts can be present as well. The diagnosis of phosphaturia must not be established upon the turbid appearance of the urine alone as some physicians are unfortunately used to doing. A chemical analysis of the urine has to show the amount of calcium to be abnormally high. As phosphaturia is thought to be a nervous disturbance and as the patients may offer signs and symptoms of nervousness treatment is that of nervousness. Apart from that it has been recommended to acidify the urine by diet and by taking diluted acids in order to counteract the formation of insoluble calcium salts and the formation of calculi which sometimes result from the deposited salts. Such treatment can at most alleviate some symptoms but does not remove the cause of the trouble. Phosphaturia (the term "calcaria-uria" is more precise and not misleading) can occur in organic nerve diseases. I found it in two cases of polyneuritis.

## CHRISTMAS IN THE SURGERY

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 25 1948

## THE SECRETARY REPORTS

### IS SPENS BEING APPLIED TO GENERAL PRACTITIONERS?

Material is being collected to answer this all-important question. The first investigation conducted in a large northern county is now complete and others are proceeding in two counties, one very rural, and in two cities, one mainly industrial and the other mainly residential. It may be useful to indicate the methods followed in making the calculations.

One first needs to know the size of the quarterly cheque for general medical services received by each practitioner on the list of the local executive council in the area. There are then added any amounts received for the same quarter by each such practitioner from any other local executive council on whose list his name also appears. Where practitioners are in partnership an adjustment is needed to calculate the amount *actually* received by the individual practitioner. In the case of the first quarter an addition of 4/88ths is necessary because the first period was four days short of a full quarter, no such adjustment being necessary where the second quarter of the year is under consideration.

Having obtained the figure of public income for each practitioner for G.P. services for a quarter—let us call it £x—it is then necessary to base on this figure a calculation of the total professional income for the year. First, it is multiplied by four (£4x), because it is based on a quarterly payment. In all cases this figure is 5% short of the total because 5% has been retained in the central fund to be paid out in some form or other in the final cheque for the year.

#### Allowance for Superannuation

It is then necessary to allow for superannuation contributions. The Government's contribution is part of the practitioner's income for the purposes of the Spens calculation. It is deferred pay in that in some form or other it will be paid to practitioners or their dependants in the form of pension, injury allowance, widows' pension, etc. A deduction of 6% has already been made for the doctor's contribution, a contribution of 8% will be made for the Government's contribution. But both percentages are applied to the net income. In relation to gross income the 6% becomes 4% and the 8% rather more than 5%. There must be added to the annual income so far calculated an amount to allow for the 4% already deducted by local executive councils for the practitioner's contribution to superannuation, and to the result rather more than 5% in respect of the Government's contribution.

So far we have reached a sum £4x plus approximately 14%—that is, 5% for retained money and 9% for superannuation. There are other additions to be made of which an exact computation is not possible. The local executive council may have kept back money in respect of basic salaries which will not be paid. There is money to be paid in respect of maternity services. There are dispensing payments for rural practitioners. There are payments to be made for vaccination and immunization, no money has yet been paid out under this heading, for, as described at p. 236 the negotiations for these payments are not yet complete. For many there is money from other sources, such as private practice, local authority work, and so on. Adding all these items together a fair estimate of the average figure to be added to the quadrupled quarterly cheque is probably about 20%, though it will vary for individuals. Where appointments are held or private practice survives the right figure may be much higher where there is no other income at all the figure will be 14%. This calculation does *not* take into account mileage payments, which on the present basis—will be twice the annual payment of pre-Act days.

#### Spens

The total professional income of each practitioner on the list of the area under investigation having been calculated it then becomes necessary to examine the result in the light of Spens, the main recommendations of which related to practitioners between 41 and 50 years of age. The next stage, therefore, is to extract the practitioners in this age group from the main returns. According to Spens, of practitioners in this age group 75% should receive over £1,000 a year, 50% should receive £1,300 a year or more, 25% should receive over £1,600, slightly less than 10% should receive over £2,000, and a small proportion at least should receive £2,500 a year. These figures are pre-war and net. Assuming, though only for the purposes of this calculation, the Government's figures for betterment—namely, 20% to the net remuneration and 55% to the practice expenses—the betterment factor to be applied to the gross remuneration is approximately one-third. Thus, to convert the Spens figure into gross post-war remuneration on this basis, one should first convert the Spens figure to gross and then add a third. In this way, £1,000 becomes £2,010. Recast in modern form the Spens requirement means that 75% of practitioners should receive over £2,010, 50% over £2,613, 25% over £3,216, slightly less than 10% over £4,020, and a small proportion at least £5,025.

These are the recommended average figures for principals, whether or not they employ assistants. In order to see the picture at its clearest, what is being done is not only to select the practitioners between 41 and 50 but to divide them up into practitioners without an assistant, practitioners with one assistant, and practitioners with more than one assistant. Broadly speaking, this is the method now being followed in the investigations under way.

Even if it were found that Spens is being applied to the country as a whole, it would not follow that it was being applied in every part of the country. It would certainly not mean that there are not cases of severe hardship which must be remedied. Yet it is clearly necessary to provide a general answer to the question, Is Spens being applied? before putting forward a case for the radical reform of the remuneration arrangements. This general consideration, however, does not apply to the so-called betterment factor. A betterment factor of one-third applied to the gross income and of one-fifth to the net income in no way represents the change in money values which has taken place. The Spens Report does not deal with the numbers on lists. Whether it is being applied or not, it is irrelevant to the question whether 4,000 is too high a maximum except in one regard. If a lowering of the permitted maximum means that a proportion of practitioners between 41 and 50 who receive the higher range of incomes is in excess of the figure recommended by Spens, then the two questions of Spens and numbers become together involved.

#### Present Hardship

Before these words appear, the Remuneration Subcommittee of the General Medical Services Committee will have met the Ministry again on the urgent question of the loss of income now being experienced by a substantial number of practitioners, including rural practitioners. They will have pressed for immediate attention to this problem, including an increase in the mileage fund, regardless of the general propositions to be put forward on the basis of the Spens investigation.

# National Health Service

## VACCINATION AND IMMUNIZATION

### FEE FOR SERVICES AND REPORT

The B.M.A. is contesting the view of the Ministry that every general practitioner in contract with the local executive council is required by his contract to vaccinate and immunize patients on his list without receiving remuneration from the local authority for this service. The views of the Association may be summarized as follows

(1) Vaccination and immunization form no part of a general medical practitioner's duties under his contract with the local executive council, but they are a statutory obligation of the local health authority

(2) Where a practitioner renders a service of this nature he should be entitled to a separate fee for the service and for any report made to the local health authority

Under Section 10 of the First Schedule to the General Medical and Pharmaceutical Services Regulations (SI 506) it is laid down that a practitioner is entitled to accept remuneration 'from any statutory body in respect of services rendered for the purpose of that body's statutory functions.' Section 26 of the National Health Service Act makes it a statutory function of local health authorities to 'make arrangements with general practitioners for the vaccination of persons in the area of the authorities against smallpox, and the immunization of such persons against diphtheria.' The Association's opinion is based on these enactments

Many doctors have already carried out a considerable number of these services and been promised that they will be paid retrospectively to July 5 as soon as agreement has been reached. The Association is urging that payment shall be speedy

## APPLICANTS SEEKING INCLUSION IN MEDICAL LIST

Many doctors applying on Form EC 16 to get on to the list of a local executive council have been worried by advertisements stating that applicants must have arranged accommodation by a certain date—sometimes only a fortnight or so after the advertisement first appears. They are also required to state on Form EC 16 the accommodation they have arranged. The Medical Practices Committee has now advised local executive councils that where an applicant is unable to furnish a surgery address at the time of completing Form EC 16 his application will be considered in the ordinary way and if granted will be subject to the practitioner sending particulars of his surgery and residence to the Committee by a prescribed date. If an applicant is unable to find a house before the required date, he should inform the Medical Practices Committee that he is still seeking accommodation, and his position will be considered in the light of the numbers of doctors then on the list. If he fails to give this information his application will be considered to have lapsed

## STANDING ADVISORY COMMITTEES THE MINISTER'S PROPOSALS

The Minister of Health has decided to set up on the recommendation of the Central Health Services Council the following standing advisory committees: Medical, Dental, Pharmaceutical, Ophthalmic, Nursing, Maternity and Midwifery, Tuberculosis, Mental Health and Cancer and Radiotherapy. The Medical, Dental, Pharmaceutical and Ophthalmic Committees will be professional in character; the others will include lay members

The Central Health Services Council (see *Journal* Aug 14 p 350) will itself set up two committees: (1) Health Centres—

To consider and make recommendations on the lines along which health centres should be developed under Section 21 of the National Health Service Act, 1946; and (2) Hospital Administration—To consider the administration and organization of the hospital services under the National Health Service Act 1946 and to make recommendations. The B.M.A. has

accepted an invitation to nominate four members from its Health Centre Committee to serve on the Council's Committee on Health Centres

Communications about the work of these committees should be sent to the Secretary of the Central Health Services Council, Ministry of Health, London, S.W.1, until secretaries have been appointed to the individual committees

## G.P. CONSULTANTS

The General Medical Services Committee and the Central Consultants and Specialists Committee have appointed a joint committee to consider matters of special interest to general practitioner specialists

The following have been nominated by the General Medical Services Committee: H. S. Howie-Wood, A. Talbot Rogers, W. D. Steel. The following have been nominated by the Central Consultants and Specialists Committee: O. E. J. McOustra, A. M. A. Moore, R. L. Newell

The committee will make recommendations in connexion with the permanent contracts of specialists, special attention being paid to rural districts where much specialist work has previously been performed by general practitioners with higher qualifications or qualified by experience to give such services

## SUPPLEMENTARY OPHTHALMIC SERVICE

The Ophthalmic Section of the Negotiating Committee met officials of the Ministry on Dec 18. The working of the Supplementary Ophthalmic Service was reviewed and a number of anomalies and difficulties discussed

## CHAPLAINS FOR HOSPITALS

The Minister of Health has asked committees and boards in all hospitals to give special attention to providing for the spiritual needs of both patients and staff. In particular they should do everything possible to arrange the hours of duty of nurses and other staff (and of students at teaching hospitals) to enable them to attend the services of their own denomination. He suggests that wherever possible a room should be set apart for use as a hospital chapel, and whatever accessories of worship are required by each denomination should be provided, and office accommodation should be provided for chaplains where possible

Committees and boards have been asked to appoint a chaplain—or chaplains from more than one denomination—for every hospital for which they are responsible, and these appointments are always to be made in consultation with the appropriate Church authorities. In some areas one whole time chaplain may serve a number of hospitals; elsewhere a part time chaplain for each hospital may be appointed

## INCREASED PENSIONS FOR CERTAIN WIDOWS

Widows under the age of 60 who on July 5 were incapable of self-support because of some infirmity and are likely to remain so for a long time can claim 26s a week instead of their 10s a week contributory pensions. They must do so before Jan 5, 1949. Any widow who thinks she may be entitled to an increase of her pension in these circumstances but who has not made a claim should obtain the necessary form of application from her local National Insurance office without delay. The address of the local office can be got at the local post office

## INTERNATIONAL HOLIDAY EXCHANGES

This scheme (*Supplement* Dec 11 p 215) relates exclusively to holidays exchanged with doctors on the Continent, and is not intended to be a means of providing holiday locums. Doctors who participate in the scheme will exchange hospitality with Continental colleagues but the scheme will not enable the visiting doctor to practise

CENTRAL CONSULTANTS AND SPECIALISTS  
COMMITTEE

## MERIT AWARDS

A meeting of the Central Consultants and Specialists Committee was held at Association House on Dec 9, with Mr R L Newell in the chair. The death was announced of a member of the Committee, Dr F B Parsons, of Cambridge, and the members stood in silence as a token of regret.

A joint subcommittee to consider problems common to consultants and general practitioners has been proposed by the General Medical Services Committee, which has nominated three members. The Central Consultants and Specialists Committee was in accord with the proposal and nominated its chairman, together with Mr A M A Moore and Dr O E J McOustra.

Attention was drawn to the fact that the Ministry had not allowed the proposed terms of service of hospital, medical, and dental staff to be circulated to regions. It was said that the Ministry had no business to interfere with the normal working of the Committee, it was imperative that the Committee should get the instructions and ideas of those it represented. It was decided that a strong representation should be made to the Ministry that permission be given for the document to be circulated to the Regional Committees.

At a previous meeting the Committee instructed its Executive to examine the resolutions of the Regional Committees on the subject of merit awards as suggested by the Spens Committee. The Committee itself had decided by a narrow majority against the principle of such awards and had asked the Regional Committees for suggestions as to alternative methods. In the regions there was a slight preponderance of support—though not qualified—for the principle of such awards.

After discussion the Committee agreed to a series of recommendations from its Executive. These accepted the principle that awards should be made for merit, subject to a satisfactory method of implementation. It was considered that the selection of 4% of the profession for awards of the highest grade should be made by a National Committee, that the National Committee should include representatives of the universities and the Medical Research Council nominated by those bodies, that it should have a lay chairman appointed in agreement with the bodies to be consulted in the formation of the committee and in consultation with the Central Consultants and Specialists Committee, and that it should from time to time publish a report of the awards made, together with the names and positions of the recipients.

It was also considered that in each region there should be established after due consultation, a committee of distinguished medical practitioners of consultant status which would select for recommendation to the National Committee specialists in the area for awards of the second and third category upon applications received from individual specialists and from other bodies.

Mr N Ross Smith placed a memorandum on this subject before the Committee and moved a resolution in which, while approval was expressed of higher remuneration for a proportion of consultants and specialists in recognition of greater ability or responsibility in the medical working of the National Health Service, the proposed method of special distinction awards was not considered to be appropriate. Mr Ross Smith preferred an establishment method with grading of appointments as to salary, and with allowances for the difference between the specialties, and for automatic annual increments of salary according to seniority within each grade. This was not agreed by the Committee.

The Committee then turned to consider the proposed terms and conditions of service of hospital, medical and dental staff on the basis of the private document already referred to which has not been allowed to be circulated to the regions. This discussion which occupied some hours, must for the time being be considered private also.

The Health Services Superannuation Division moves on Dec 29 from 28, Prince's Gate London SW7, to Government Buildings, Honeyport Lane, Stanmore, Middlesex. The new telephone number will be EDGware 2311.

## HEARD AT HEADQUARTERS

## That Extra Work

One or two opinions have been gathered informally from practitioners in the provinces on the attitude of patients to the new Service. One doctor in the West Riding said that the Service so far 'has realized neither our worst fears nor our highest hopes'. All of them spoke of busy surgeries, but on the whole they paid a tribute to their patients which it is refreshing to hear. One of them noted the hesitating approach of some patients, like the housewife who said "It doesn't seem right to get all this for nothing". But, of course, the practitioner's work is multiplied by the family. As one doctor put it: "The mother comes along pushing one child in front of her and dragging another behind, and when you have looked into the first one's throat trouble you are asked to stop the second one's cough, and finally the mother says, 'And while you are about it, doctor, you might just look at this elbow of mine'." No doubt treatment of trivial ills is being asked for on an unprecedented scale. From this small inquiry—concerning not more than a dozen provincial doctors in busy practices—it seems that patients are very often considerate, patient, and careful of the doctor's time.

## Doctors' Handwriting

The badness of doctors' handwriting is an old joke, and Mr Chuter Ede, the Home Secretary, brought it out again when distributing prizes to commercial students the other evening at the Albert Hall. Some of the prizes were for excellence in handwriting and Mr Ede remarked that quite clearly the prize-winners would never be doctors.

## Dental Priorities

The fantastic situation in dentistry is worrying the London County Council. The priority service for expectant and nursing mothers and children is jeopardized by the resignation of dental surgeons in the public service to take up more lucrative private practice. The total strength of the LCC dental service has been reduced by nearly one-third, and twenty dental centres have been closed wholly or in part, while there is little immediate prospect of staffing 20 new centres which are ready or almost ready for use. Such a loss of dental surgeons appears to be higher in London than in the rest of the country, and other local authorities have intimated that they would not object if the LCC finds it necessary to meet the situation by an increase in the salary scale over and above the small percentage increase now being granted generally in the country. It is therefore proposed to raise the maximum of the scale for LCC dentists to £1,250 as from the beginning of December. The maximum to which a dentist can rise at present, with the recent Askwith percentage increase, is £1,050.

## Equal Pay

An inquiry has been made of medical officers of health about the question of equal pay for men and women medical officers, and also the consolidation addition or bonus payable. So far replies have been received from 144 county borough, and metropolitan borough councils. Of this number 27 employ no women medical officers, 73 have a system of equal pay, 14 of unequal consolidated addition, and 20 of unequal bonus. Of 96 municipal boroughs which have so far replied 71 have no women medical officers and 20 of the remainder have a system of equal pay. A further letter calling attention to the BMA equal-pay policy has been sent to all local authorities now known to be differentiating between men and women medical officers as regards payment of consolidation addition.

## Report on Nutrition

Another interesting BMA report is being drafted. The Nutrition Committee set up by the Council appointed a clinical subcommittee, which has prepared a report examining critically the information available on the state of health of the community and the effect of wartime diet on health. The subcommittee's conclusions must not be given before they are endorsed in their final form, but in general after allowing for the sparseness of information in some fields, and the difficulty of collecting clinical data for certain groups, our food policy

seems to be justified by such statistics as can be applied. The subcommittee has been unable to express an opinion on whether or not the nutrition of the industrial worker is or has been sufficient to enable him to respond to all the calls made upon him.

## Questions Answered

We publish here the answers to a selection of questions that seem to be of general interest

### Specialists Spens Report

**Q**—I have heard that the Government has issued its proposals for interpreting the Specialists Spens Report and for the conditions of service of specialists and consultants. If this is true why have you not published them?

**A**—The proposals have been issued, but the Ministry of Health will not allow them to be published.

### University Employee and Superannuation

**Q**—I am employed on a yearly contract by the university as registrar and tutor and the greater part of my work is carried on in the out-patient department of a teaching hospital. Am I liable for NHS superannuation payments?

**A**—A practitioner employed by a university is not subject to the NHS superannuation scheme.

### Assistantship with View

**Q**—I have recently been offered an assistantship with view. The question which occurs to me is whether or not the existing partners who are taking part in the NHS are in a position to offer a view. Or is the successor to a position of the partnership a matter to be decided entirely by the local executive council? If they are in a position to offer a view what is the nature of the usual type of contract?

**A**—An assistantship with a view is for practical purposes a partnership with a period of preliminary assistantship on a probationary basis. To employ an assistant for more than three months the consent of the local executive council is required. To secure inclusion in the medical list of an executive council the consent of the Medical Practices Committee is required. The only ground on which the Medical Practices Committee can refuse admission to the list is that there are already enough general practitioners in the area.

The Minister has given the following assurances: (a) All will be free to choose colleagues, partners, and assistants unless the area requires no more (on the decision of the Medical Practices Committee) or the regulations on the employment of assistants are contravened. Where more than one doctor wishes to be the partner or assistant in question, the Medical Practices Committee will be asked to observe the wishes of the doctors concerned. (b) Doctors will be free to decide when an additional partner or assistant is necessary subject to the cases where the Medical Practices Committee decides that no additional doctor at all is needed in the area and subject to the conditions about assistants. (c) Except in areas which have been declared 'closed' by the Medical Practices Committee the consent of the Medical Practices Committee will be given automatically to applicants seeking inclusion in the list.

In areas which have not been declared 'closed' by the Medical Practices Committee a practitioner or a partnership is in a position to offer an assistantship with a view. In an area which has been declared 'closed' this will depend upon the attitude of the Medical Practices Committee after consultation with the local executive council, which in turn consults the local medical committee. It would be reasonable to expect that even in a closed area the Medical Practices Committee would approve the application for inclusion in the list of an assistant who was taking over from an outgoing principal or partner. Where the executive council and the local medical committee are of the opinion that a practitioner is the natural successor, a block transfer of the outgoing practitioner's patients may be made to him.

Agreements vary according to the wishes of the practitioners concerned and the principal or partner and the assistant would be well advised to seek the advice of a solicitor with experience in medical agreements.

## Correspondence

### Drugs Stocked by Doctors

**SIR**—I note that the discrimination between English and Scottish practitioners over the use of Forms EC 10 and EC 10A has been the subject of a Parliamentary question, and that the Minister has replied that he sees no reason for altering the present arrangements. He is hardly likely to see reason for this or any other reform unless it is forcibly put before him, but if the reasons for the present arrangement were explained to the profession they might find it less irksome.

The arrangement in force in Scotland allows doctors in the NHS to order on a special Form EC 10A stocks of such drugs and appliances as are required (a) for immediate administration or (b) for use before a supply can be obtained by means of a prescription and (c) any other drugs which are administered by them in person. How are English practitioners to obtain such supplies? In theory they are apparently expected to buy them with their own money, and are allowed for this purpose 2s 6d per 100 persons on their list—£5 per year for the man with 4 000 patients. As this is manifestly absurdly inadequate to cover all supplies coming under the three categories, and as most of us are probably a bit hazy as to what the 2s 6d per 100 is actually supposed to pay for, we presumably most of us try to keep up our stocks by over-prescribing for one patient so as to have stock available for the next.

Obviously under either arrangement there has always been a possibility of using public supplies for private patients, but now that private practice is so largely obsolete there would seem to be no excuse for continuing this untidy effort to keep English doctors as honest as their Scottish colleagues are assumed to be. To regularize the bulk ordering of an adequate stock of the supplies concerned would be a real help to the already overburdened doctor. But it would also ease the burden on the chemist and the patient. With all dispensing in urban practices suddenly shifted to the chemist he is often unable to give the urgent prescription the priority it needs and treatment may be delayed for hours or even days. Much more of this urgent dispensing could be done at the doctor's surgery as of old with advantage to all concerned. But unless the use of form EC 10A is conceded to English doctors no doctor can be expected to provide more than the niggardly minimum which can be assumed to be covered by the 2s 6d per 100 per year. And we shall all continue to try to keep up our stocks by such unsatisfactory methods as those indicated above, never sure whether we are robbing ourselves or the State. Is there any reason why the Minister should not regularize the position at once? If there is, is it too much to ask to have it explained?—I am, etc.,

Chelmsford Essex

IVOR BEAUCHAMP

### Value of Money and Compensation

**SIR**—With reference to the sum of £66 million the agreed figure to compensate for all general practices I have seen no mention in the *Journal* of any adjustment which in equity, must be made in this figure for the changed value of money since the original negotiations. If compensation is not to be made with reference to the market value of practices it should surely be adjusted to the current value of money—I am, etc.,

Wimborne Dorset

K B CLARKE

### Earnings of Specialists

**SIR**—A faint flicker of hope was raised in my despondent bosom by Dr S Balfour-Lynn's letter (*Supplement* Nov 6, p 166) and the letter from Mr Deitch (*Lancet* Nov 6, p 747). One began to think that at last a few specialists were realizing the desperate plight in which we have been landed. However from the lack of comment since, I have relapsed into despair.

To console would-be specialists I can summarize most of the Spens Report for them. After the postgraduate years of study mentioned by Dr Balfour-Lynn they will be employed, if fortunate, on a salary equivalent to that of a clerk to the management committee and rather more than half of what their general practitioner colleagues receive. After eight years they will rise to a maximum of somewhat less than a general

practitioner might receive This maximum, for two-thirds of them, will be permanent In addition they will be taxed on this salary under Schedule E, which means that their net income will be very considerably less than a general practitioner, who gets his professional expenses allowed under Schedule D—I am, etc ,

Dartford Kent

G DALLEY

### Large Lists

SIR,—In letters of late scorn has been poured on those doctors who through good fortune or merit have neared or attained the maximum number of patients Such epithets as "swollen lists," "head hunters" etc, have been bandied about I would remind these writers that these patients required medical attention before the Health Service and received this for small fees and often for nothing Naturally they have wished to continue with their own doctors, and they have come of their own free will without pressure or inducement Was it wrong of us to treat all these patients before July 5, or has it only become an offence since then?

To penalize such doctors a sliding capitation fee is proposed The Representative Body of the BMA has always voted against differential rates of payment In my opinion such a system would be illogical, unfair, and unwise If it is wrong for a doctor to treat more than a given number of patients for a fixed capitation fee, how can it be right for him to treat the same patients for a lesser capitation fee? It would be unfair, for I do not know of any worker who is paid less for more work done It would be unwise because, once the principle of a variable capitation fee were established, it might be put to other uses For instance, practices in beauty spots or health resorts amid pleasant surroundings with clear skies and pure air might be rated at  $\frac{1}{2}$  to  $\frac{1}{4}$  the basic fee, while practices in the grimy hearts of our industrial cities might be rated at  $1\frac{1}{2}$  to 2 times the basic fee Several other interesting variations can be worked out

The suggested maximum of 2,000 is impossible at present Taking into account sparsely populated areas, over-doctored areas, and the practices of doctors who through age, ill health, or for private reasons have small lists, the average elsewhere will be over 3,000 In any case there would be anomalies How should the numbers on the lists of two doctors compare? One devotes himself entirely to his practice, does not apply for inclusion on the special midwifery list and has no outside posts, and the other is on the special midwifery list and has various outside posts—hospital, industrial medical officer, pension boards, police surgeon, medical boards, etc

The foregoing is not an attempt to excuse the inadequacy of the present capitation fee but a plea that future writers consider this on its merits and not attempt to penalize or defame a hard working section of the medical profession—I am, etc, &

Birkenhead Cheshire

A V RUSSELL

### Threaten to Resign

SIR,—I heartily endorse the sentiments expressed by Dr William R Mackie (*Supplement* Dec 4, p 209) The situation is intolerable, and if not immediately remedied calls for a 90% resignation To work a seven day week with numerous night calls and 24 hours on duty and find at the end of the quarter that one's cheque is exactly half the monthly cheque of a dental colleague is more than human flesh can bear The complacency of the recent BMA circular merely fanned the flames of indignation—I am, etc ,

Inverleithen Peeblesshire

G NEIL FLETT

### Resign or Emigrate

SIR,—I heartily endorse Dr William R Mackie's letter (*Supplement* Dec 4, p 209) with regard to the plight in which doctors are at the present time The remuneration for a practitioner with a small practice is totally inadequate, and doctors of experience who have to work longer hours in days of rising costs and where the pound has only the purchasing power of 5s if that as compared with pre-war should be properly compensated to enable them to give of their best to their patients The alternative to a refusal by the Ministry to give adequate living facilities to men who have spent a lot of time and expense in acquiring their skill and experience seems to be a wholesale resignation from the scheme and a return to private practice, or alternatively emigration—I am, etc

Croydon Surrey

J A H SYKES

### Details of Service

SIR,—I cannot help feeling that we ourselves are mainly to blame for the burden of Atlas which is now laid on our shoulders While I consider that the BMA was right to suggest we joined the Service, I think that the Negotiating Committee was wrong not to have discussed details of service, and I wrote a letter to that effect which was published in the *Supplement* (Nov 29, 1947, p 127) while negotiations were going on, but not one letter was written in support, though now many of your correspondents are complaining about this very matter I know the committee said they had no mandate to go into details of service, but this hardly seems a far-sighted or realistic policy

The BMA has some able and hard-working men in its ranks who are distributed and dissipated among its all-too-numerous committees and subcommittees What we now need is a much more ruthless and realistic organization, a trade union, with only one committee consisting of some very hard-faced men whose foremost task is to better the conditions and pay of the medical profession, which we are all agreed are most unsatisfactory—I am, etc ,

Worsborough Dale Yorks

D W MAYMAN

### Remuneration

SIR—I wish to add my protests about the National Health Service in its present form to those of other correspondents on this subject Like many another I entered the scheme in July with many misgivings but determined to do my best to make it work I state at once that I entered the Service because I could not afford the loss of capital which failure to join would have entailed—capital which I had invested in the purchase of the practice originally, and increased by dint of hard labour and the giving of good service to all patients whatever the patients could afford to pay As a result of these efforts the capital value of my practice doubled itself in as many years With a stroke of the pen and the passage of five months my efforts are nullified and my financial position is at the stage it was four years ago Not only is this a bitter pill to swallow but in addition the deterioration in the standards of practice which the present system has brought about is depressing and makes it impossible to tackle the problem of the sick without the caring care of financial insecurity

I have maintained from the very outset that, while the dignities and freedoms of our great profession required every effort to safeguard them, the fundamental principle of proper remuneration was never given its proper place or perspective in the discussions which dragged on interminably until we were advised to take service No man—with the best will in the world, and filled with the desire to give of his best—can do so with the wail howling at the door its cries becoming louder and louder as the end of the quarter draws nigh

I have no doubt that those practitioners who enjoy—if that be the word—huge lists of patients will at once refute the charge, but I am quite convinced that no man can possibly look after 4,000 patients adequately or properly It is a complete fallacy to pay to a man, who by virtue of numbers can devote some ninety seconds to each patient in his surgery, the same amount as is paid to a man with smaller numbers, especially when his patients expect more attention and demand the same detailed examination and service as when they paid 10s 6d or more for it This point, in my view is not stressed sufficiently, but is of great importance when the question of remuneration is under review

The cost of living—in spite of the denials of the present Government—rises steadily and inexorably to maintain a medical establishment in what is known as a residential area costs far more than in an industrial or country area At the same time it is impossible to attract the grotesque numbers found in industrial areas or even the sop of increased mileage allowance in rural areas—for what that is worth

I am afraid that the wretched attempts made during the pre-July-5 period are being and will be continued unless some definite plan or decision is made No other body of men would have allowed themselves to be manoeuvred into our present position no other body of men will make less effort to get out of the mess unless forthright methods are adopted—this in spite of our tremendous powers, for without us the entire Service must collapse

I suggest (1) that the BMA notify all Branches of the Association to hold emergency meetings during the next month with the specific purpose of ascertaining the temper of its

members, (2) that at these meetings the only subject to be discussed is the pay of doctors, (3) that the BMA propose through each Branch chairman to recommend full resignation from the Service unless the capitation fee is at once raised to £2 per caput, and voting take place on this motion without delay, (4) if the BMA is not prepared to do this, that we form local groups who are prepared to act independently.

Surely the spectre of the vicar or curate striving to save souls on a miserable pittance with the liability of a huge unworkable house and a wife and family to keep is a sufficiently dreadful example of what inadequate payment can produce. I hold the view that, while duty to medicine and one's patients is a grave responsibility, yet the duty to one's wife and family is even greater. Charged with these responsibilities, it is a wretched man indeed who will not take up the cudgels in a warlike mood. Let us stop at once our representations, suggestions, and recommendations and begin our demands. Until we are prepared to act in this way I am convinced that worry, misery and over-drafts will be our lot—I am, etc.,

Beckenham Kent

R E NEWMAN

### Payment for Work Done

SIR,—The recent decision of the Minister of Health to alter the payments to dentists has no doubt been noted with some foreboding, by the majority of your readers. This action involves the use of two new and reprehensible principles: first, that a man should no longer be paid for the work he does but be paid for that work in relation to an arbitrarily fixed income level. The old trade union standard of 'the rate for the job' has been abandoned. Secondly, as far as we of the sister profession know, this action has been taken with little or no pretence of consultation with the workmen involved.

Add this new departure to the practice already established of asking men to do a job first and 'discuss' the rates of pay later, as has happened to consultants and specialists in the hospital service, and to the first denial of the promise that a citizen may use all or any part of the Service, for which he pays, at will, and one can then build up a picture of the 'no foul rules' in this game with the Minister that the Association so rashly hurled us into. Note too, Sir, that there is no referee in this game, no half-time, and no final whistle. The crowd may boo, but they cannot get their money back—I am, etc.,

London SE 15

P G McGRATH

### Solid Work at Periphery

SIR,—We are a strange profession indeed. On reading the belated blarneys in the *BMJ* one would think that many are surprised at what are really logical sequels in a service the control of which we have almost entirely lost. The BMA has made obvious blunders—e.g., discussion (provisionally) of compensation terms at far too early a date, allowing a panic second plebiscite before the profession had time to consider it, a futile effort to retain goodwill of practice and so on, but had the bulk of the profession had the foresight and the courage of the Chairman of Council we would not be enslaved as we are to day. Let us therefore accept once and for all that the profession caused its own downfall by not giving its leaders a clear mandate proved by a weak response to the Defence Fund.

A recent correspondent states that we were forced to sell our practices. May I ask who forced us? I cannot but wonder how many who were so lukewarm in their support for retention of goodwill now feel that freedom of movement was a principle worth fighting for and how many weary members of local medical and executive council committees consider that the mythical problem of distribution of doctors has in any way been solved. Do the new applicants for practices feel that the new system is an improvement on the old? It is depressing to think that even now we do not realize that had we won the principles we could not have lost on the regulations and detail.

Let us not dissipate our strength on recriminations and selfish arguments about sliding capitation fees etc., but stick to the principle that a capitation fee must be adequate per person no matter the numbers on a list otherwise we are playing into the Minister's hands to cheapen an already cheapened

service. We can expect no help from the politicians of any party. We know that all parties agree that it is a good thing for the Minister of Health to buy and sell our patients, but two parties only believe that it is a moral crime to nationalize steel.

I write in the hope that we cease our internal bickerings and direct our every effort through the BMA as our only hope of salvation. It is not reorganization of representative election of our leaders that we need but solid work at the periphery—the groups, the non-attenders, and non-talkers at meetings. There is only one answer to any Ministerial argument, and that is mass resignation and I feel and hope the call will come to find us united and add fuel to the beacon Lord Horder has kindled—I am, etc.

Sheffield

ANDREW STEPHEN

### Unemployment

SIR,—Being a potential general practitioner under 35 years old I should like to draw the attention of the BMA to some of our difficulties in seeking work.

(1) The replies I have received from general practices in the area in which I seek work point to the fact that although overworked they cannot take on extra commitments due to financial insecurity.

(2) Trainee assistantships under the NHS appear to be the main source of work and they are not open to me due to previous experience in general practice.

(3) The advertisements for vacancies in general practice from the local executive councils average two to three a week, and these expect from the applicants more than should be asked. For example, from the *BMJ* of Nov 27 (a) Stornoway—applications and testimonials by Dec 11, and for a potential panel of 3 500 one is expected by the authority to provide an extra surgery, and an assistant may also be needed, (b) Newcastle upon Tyne—applicants are expected to apply on a special form and arrange provisional accommodation all by Dec 4.

Thus are we faced with unemployment in a new NHS scheme the advocates of which said that it would aid those setting up practice for the first time, so do we have to suffer under a scheme for which so many of us did not vote.

It is up to the BMA to set these things right with all possible speed, but how are they able to bring any pressure to bear in the negotiations with the Minister now that he has us all in it whether we like it or not? In fact do they really represent fairly the position of the general practitioners? The new arrangements about the basic salary point to the fact that they do not—I am, etc.

Greenhithe Kent

MARGARET DUDLEY-BROWN

\*\* The Association has established a special organization—the Medical Practices Advisory Bureau, BMA House, Tavistock Square, London, WC1—to provide information and advice on available opportunities and openings in general practice.—ED *BMJ*

### Remuneration an Urgent Problem

SIR,—The BMA prior to the final plebiscite would have us believe that, unlike the leopard Bevan had changed his spots, and that henceforth he was going to beam benevolently on the BMA and the profession in general if only the former would persuade the latter to sign on the dotted line. The dentists were a little more resistant, especially as compensation for goodwill did not arise in their case and they had been told outright that no amending Act could be expected. However, the inevitability of the implementation of the Act, in its original form virtually, after the surrender of the BMA, and perhaps the glittering financial prospects persuaded the vast majority of dentists into the scheme like us against their better judgment and conscience. Now comes their rude awakening. However, their 'ceiling' of £4 800 still leaves them comparatively well off. I would willingly forfeit 100% in excess of a much lower figure were there any possibility of attaining it.

I enclose a cutting from the *Daily Telegraph* (Dec 7) under the heading 'Doctors' New Fees Demand'. In this I learn that the General Medical Services Committee of the BMA has under consideration the recommendations of the Conference of Local Medical

Committees, which met in London on Nov 25, on the subject of remuneration. After the next "interim", cheque the B.M.A. (the article goes on to state) will then survey the doctors' financial position. Sir, the financial position of the bulk of the doctors is only too evident and, unless the B.M.A. is more out of touch with its members even than I suspect, it must be moderately clear to them.

The article further states that Mr Bevan, through his officials (he no longer deems the courtesy of a personal appearance necessary), met a deputation on the subject two weeks ago. And here I quote, "He is not likely to make any final decisions until the winter is over. It is an urgent matter to put a stop to the dentists' high earnings, but to raise the doctors' miserable pittance can wait until the stress and strains of the winter epidemics are over. Then he thinks he will no longer need us for a spell, except to issue an occasional optical certificate, which does not matter anyway, since he is short of lenses."

Sir, the subject of remuneration is urgent. Dr Cockshut says so, and, what's more, produced evidence. And feeling must be running strong if the Chairman of Council can go so near to the mention of "strike" as "withdrawal of service" on this issue. We do not want to subsist on charity as exemplified by basic salaries and special inducement payments. All we ask in return for a more than honest day's work is the fulfilment of a promise of a liberal interpretation of the Spens recommendations. Otherwise, from the depths of the Slough of Despond into which many of us are rapidly descending, we cannot possibly "deliver the goods"—I am, etc.,

Penn Wolverhampton

A. E. ROBERTS

### Betterment Factor

SIR—According to your note in the *Supplement* of Nov 27 (p 192) the Ministry is using a betterment factor of 20% applied to net remuneration. Practice expenses have increased by much more than 20%, perhaps by more than 66%. No allowance appears to have been made for this increase in expenditure. In a practice where expenses were one-third of the gross income of the Spens 1939 15s represent overhead charges and should carry an increase of say 66%. 10s, the net remuneration portion of the capitation fee, carries the betterment factor of 20%. So that at 1948 values of money a capitation fee worth 15s in 1939 should amount to £1 0s 4d if it is properly to show a betterment of 20% on net remuneration.

By comparison the present capitation fee after deduction of amounts for the mileage pool and basic salaries, may amount to 17s 3d. When expenses, properly weighted for the increased costs, are deducted a net remuneration of less than 9s remains. This shows that a "worsening factor" of some 10% has been applied. That these figures are not purely theoretical is shown by my own and no doubt many other practices.

By its reference to other middle-class incomes the Spens Report may not entitle us to demand that our remuneration should carry a betterment factor equal to the whole of the rise in the cost of living. At least we must insist that the whole of the increased costs of running our practices are added to the capitation fee and that then an adequate figure to cover increased cost of living is added to net remuneration—I am etc.

Clevedon Somerset

W. H. HYLTON

### Time Spent on Committees

SIR—The amount of time spent by medical practitioners at committee meetings is giving rise to considerable misgivings. The type of man likely to possess those qualities of most value in committee is frequently he who is most successful and sought after in his own practice. It will include the senior members of the profession. He may serve on an area hospital management committee and on the medical board of one or more particular hospitals. These are likely to meet at least once a fortnight. Such a man must attend an important committee meeting once a week which may last three hours. Furthermore for one who takes a serious view of the proceedings and studies the agenda beforehand those three hours may be considerably less than the time spent on this matter out of committee. The times of the meetings must be fixed out of "ordinary" working hours, so that these men are often out after midnight in bad weather having already completed a heavy day's work.

I have not been able to follow all the correspondence in this *Journal* but I have not seen this problem seriously raised

I feel it is time that someone proposed a vote of thanks to those members of the profession who have been called upon to plan the local medical services of this country at the expense of the already rapidly diminishing time they are able to spend at home with their families—I am, etc.

London SW 1

P. F. LUCAS

### Implement Spens Report

SIR—I was interested to read to-day the basis of remuneration of our dental colleagues in the N.H.S. I quote from the *Daily Express* of Dec 6 "A Ministry of Health official said. It was provisionally agreed that the gross income on the basis of a 33-hour week, should be £3 800 a year, but because there is a shortage of dentists the figure now taken is £4,800."

I appreciate that, say, a dental extraction is a much more highly skilled procedure than completion of a certificate for glasses or for a truss, but I still feel that some degree of parity of remuneration would appear to be indicated. My own 70+-hour week would then produce an income in the region of £8,000 per annum. A small step towards this goal would be immediate Governmental implementation of the Spens Committee Report.—I am, etc.,

Woodbridge Suffolk

P. DAWNEY

### Estimate of Income

SIR,—Dr A. S. Morton Palmer (*Supplement*, Dec 11 p 223) questions Dr Charles Hill's assertion, repeated in your leading article entitled "N.H.S." (*Journal* Nov 13, p 864) that the total pre-war income of general practitioners amounted to £28 million. There is a further assertion in the same leading article which seemed worthy of investigation—I.e.

"In an industrial country such as Britain the majority of general practitioners will receive the greater part of their income from what were formerly described as 'panel patients'."

For this purpose I decided to ascertain the incomes of practices (and their respective panels) advertised for sale at a pre-war date. To secure a "random selection" I obtained several *B.M.J.s* of the spring of 1938 from the B.M.A. Library and chose the first that I picked up. I made a note of (a) the annual income of "mixed" panel and private practices (b) the number of panel patients associated with each, and (c) the annual income of practices advertised as either without panel or with a number of panel patients unspecified (which can reasonably be assumed to be not very great).

The figures arrived at, in round numbers, are (a) Total income of "mixed" practices £148,000 (b) Total number of panel patients 105,000 (c) Total income of mainly non-panel practices £23,000. Number of "mixed" practices 89. Number of mainly private practices 16. Hence in these 105 practices the total income was £171,000, with total number of panel patients about 110,000.

Having regard to the capitation fee paid in 1938 it appears that this assertion has no foundation in fact and that the inference drawn from it is unwarranted—I am, etc.,

London SW 3

—MORRIS CUTNER

\*\* The figure of "rather more than £28 million" is not the Secretary's "assertion" but a mathematical computation based on several thousand statements of doctors' incomes used by the statistician, Professor Bradford Hill, in the preparation of the Tables submitted to the Spens Committee.—ED. *B.M.J.*

### Shift of Income

SIR—No doctor can attend a full list and do his work well without breaking down in health. Thus all those doctors who are interested in maintaining a high standard of medicine should press for a reduction in the lists. The clock puts a limit on the amount of work a doctor can do. It takes an equal amount of time to care for 1,000 patients in the country or 2,000 patients in a residential area or 4,000 patients in a slum industrial area. Unfortunately these three different types of practices do not bring in equal incomes. Remuneration in the National Health Service bears no relation to work done. There has been a "shift" in medical incomes and a new aristocracy has arisen. The successful doctor of yesterday with a large private practice and a modicum of panel patients

who has to give way to the doctor who used to have a large hotel and club practice. It used to be the ambition of every doctor to pass from the latter class to the former, now the process is reversed. It is not a struggle between the "haves" and the "have nots," as Dr J M Bellamy (*Supplement* Dec 11, p 220) suggests but a struggle of those who used "to have" and now "have not" any longer. These men are in a tragic plight and have to seriously lower their standard of living. Their only offence is that they have been accustomed to 'good doctoring'—I am etc

Newcastle upon Tyne

H H GOODMAN

## POINTS FROM LETTERS

### Unreasonable Deductions

An ENGLISH DOCTOR writes: In my opinion the only reasonable deduction allowable from a medical practitioner's remuneration is the 6% for superannuation. Now that 98% of private practice has gone the vast majority of practitioners have sustained a very severe reduction in their incomes, and in some unhappy circumstances many of our colleagues have been reduced to a state bordering on bankruptcy. It is absolutely absurd that from a common pool there should be a deduction for mileage, this is simply taking from one hand to put into the other, or robbing Peter to pay Paul. What this simply means is that one section of the practitioners' community has this amount of mileage money deducted from their legitimate fees in order that their country brethren be paid the mileage scale. Another deduction is the £300 per annum basic salary. It is odious for the unfortunate doctors in receipt of this beggarly sum to know that it is being deducted from the salary of their perhaps slightly more fortunate brothers, and it is grossly unfair that this sum should be deducted from the capitation fee, it should be paid in an honest straightforward manner by the Treasury. In exactly the same way all expenses of medical committees, local or national, which are doing work for the State and the State doctors, should be paid from the Treasury. These expenses should not have to be met out of the pockets of the underpaid penalized doctors.

Personally I am perhaps slightly more fortunate than a lot of my colleagues in having some 3,000 odd patients on my list, but even so with this number of patients I have been compelled to take my 16-year old daughter away from school because I simply cannot afford £250 per annum for her education as well as for my son's. The girl's career has suffered, as she would have stayed on at school until 18 and then gone up to the university, but I cannot do it for both my children.

It seems to me fantastic that the B.M.A. should have allowed such a state of affairs to come to pass and must go to show the gross incompetence and lack of business experience of our negotiators. I also cannot understand why Branch and Divisional meetings are not being held all over the country in order to agitate and make known publicly through the Press in the strongest possible terms the disapproval of the profession to the scheme as at present constituted.

### Ichabod

Dr A R STUART WARDEN (Brighton) writes: A few days ago a young woman came into my surgery and asked for a form to have her eyes examined. I asked her if she was registered with a doctor, and she replied, "Yes, but I don't know who the heck he is, and any doctor will do for this."

## Association Notices

### SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of 50 guineas, is again open for competition. The following are the regulations governing the award:

1 The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice, it includes a money award of the value of 50 guineas.

2 Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3 The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4 Essays, or whatever form the candidate desires his work to take must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec 31, 1948. The prize will be awarded at the Annual General Meeting of the Association to be held in 1949.

5 No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.

6 If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7 Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

8 The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

9 Inquiries relative to the prize should be addressed to the Secretary.

### KATHERINE BISHOP HARMAN PRIZE

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1949. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1949, but will be offered again in the year next following this decision and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine.

The decision of the Council will be final.

Each essay must be typewritten or printed in the English language must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed at B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec 31, 1948.

### MIDDLEMORE PRIZE

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate, and was founded in 1880 by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1949 to the author of the best essay on "The Value of Orthoptics in the Treatment of Squint." Essays submitted in competition must reach the Secretary, British Medical Association B.M.A. House, Tavistock Square, London, W.C.1, on or before Dec 31, 1948. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1949.

### Diary of Central Meetings

JANUARY

12 Wed Council, 10 a.m.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar  
*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), WallSEND

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley

## INDEX TO VOLUME II FOR 1948

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate headings—for example, Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Renal and Kidney, Cancer and Carcinoma, Child and Infant, Gout and Thyroid. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Annotations," Correspondence, Leading Articles, Obituary, Reviews, etc. Original Articles are indicated by the letter (O).

A

- [illegible]

- Amputation iostantaneous traumatic forequarter of right arm (J D C Millar) 559 correspondence 662 722 876 879 1122
- Anaemia cirrhosis of liver presenting as severe anaemia (P N Coleman) 858 (O)
- aplastic in Simmonds's disease report of case (Arnold Bloom and Charles C Bryson) 75 (O)
- hypoplastic 584
- macrocytic 153—In eunuchs 186—Of pregnancy 225—Crystalline anti pernicious anaemia factor in treatment of two cases of tropical macrocytic anaemia (J C Patel) 934 (O) annotation 949
- pernicious Crystalline anti pernicious anaemia factor in treatment of two cases of tropical macrocytic anaemia (J C Patel) 934 (O) annotation 949
- ANAESTHESIA
- Abdominal relaxation 92
- Book review 747
- Caudal extradural block 92
- Chest surgery anaesthesia for 91
- Intravenous in dentistry 967
- Intubation in infants 92
- Procaine intravenous in transfusion (G S W Organe and C F Scurr) 787 correspondence 1036
- Thiopentone and curare solutions Apparatus for continuous administration (R Atwood Beaver) 1032
- Tonsillectomy 1047
- Trichlorethylene auricular fibrillation after (J B Ewing and G J C Brittain) 904
- Trilete Convulsions under (H A Condon) 340—As an analgesic 620 691 761
- Vomiting post anaesthetic 725
- ANALGESIA
- Alcohol injection 587
- CB 11 a new analgesic drug (W M Wilson and R B Hunter) 553 (O)
- Cordotomy 589
- Epidural block 589
- Intraspinal sulphate injection 588
- Metycaine 92
- Midwifery analgesia in 50 155 356
- Paravertebral block 589
- Pethidine and scopolamine in labour (Hilda Roberts) 590 (O) annotation 607
- Spinal 92—Meningitis following 445—Respiratory depression during 957—And caesarean section 1121
- Stellate block in pulmonary embolism (annotation) 608
- ANAPHYLAXIS 281
- Anastomosis methods of in partial gastrectomy for peptic ulcer 1095
- Anatomy Pars nervosa of pituitary 119—Cremasteric vessels 135—Ape skull of the mucrone age (W E Le Gros Clark) 951
- of primates present state of our knowledge (F Wood Jones) 167 629 (O) correspondence 763
- surgical of parotid gland (Hamilton Bailey) 245 (O) correction 364 correspondence 443
- Anthraxoma infestation persistence of 1090
- ANDERSEN A Harrestrup Sensitization to sulphamides 837
- ANDERSON Graham H Laurence-Moon-Biedl syndrome 517 (O)
- ANDERSON H A (and others) Pharmacology and Experimental Therapeutics 748
- ANDERSON T (and others) Purpura fulminans complicating scarlet fever 5-9 (O) correspondence 661 916
- Andrew George obituary notice of 403
- ANDREW G S Diagnosis of gonorrhoea 42
- ANDREWS C H Prophylaxis of virus infections with special reference to use of vaccines 159 100\* (O)
- Andrews reversion of changes caused by 407
- Andrews aortic dissection surgical significance of report of 3 personal cases with 2 correct ante mortem diagnoses (D P van Meurs) 599 (O) correspondence 696
- cerebral 574
- splenic and gastric enlargement in pregnancy (H L Strachan and Norman M Falkner) 1105 (O)
- Angio-oedema and vitamin M (Falkner) 1105 (O)
- precocious New conception of 53 108—Spasmodic 155
- Vitamin 5, pernicious for 60
- ANNAS W G Treatment of fungus infection of 12

## Annotations

- Abdominal distension and DFP 719  
Abscess cerebral and congenital heart disease 868  
Acanthomycosis treatment of 830  
Air accidents human factor in 261  
Anti adrenaline substances 950  
Apothizamine drugs and gastric secretion 1025  
Anomalous excretion of 83  
Anu pernicious anaemia factor 949  
Aorta thoracic permanent intubation of 688  
Arsenic as a cause of cancer 912  
Arthritis rheumatoid course of 912  
Artificial limbs improvements in 565  
As may be required of him 795  
Bacteriological examination of shellfish 35  
BAL more research on 1072  
Bile white again 794  
Blood circulating distribution of 608  
British Journal of Industrial Medicine 525  
Cadmium toxicity of 33  
Cancer Cells in sputum and urine 83—Arsenic as a cause of 912  
Carcinogenic action of liquor picis carbonis 608  
Chemotherapy Of filariasis 52—Of undulant fever 1113  
Children Fatty liver disease in 213—Protecting children from tuberculosis 346—Child Health Services 453—Removal of tonsils 564—Lead poisoning in 609—Kerosene poisoning in 688—Oral penicillin in 867  
Colour terminology 145  
Coronary insufficiency acute 1027  
Diet and production of ascute 1027  
Diphtheria lungs in 260  
Disk lesions location of 430  
Empire Medical Advisory Bureau 211  
Erythrocyte inclusion bodies of the, 431  
Fertility differential 34  
Filariasis chemotherapy of 32  
Food preservation 82  
Gastritis giant hypertrophic 145  
Genetic component of language 347  
Glandular fever and nervous system 566  
Heart Voluntary acceleration of 394—Slight enlargement of 687—Cerebral abscess and congenital disease 688—Origins of cardiac pain 911  
Heberden's nodes 34  
Hernia femoral 750  
Histamine liberation of by curare 212  
Hypertension New factors in shock and 346—Biochemical changes in 565  
Indexes half yearly 431  
Industry Health of arc welders 81—Dermatosis in paint industry 215  
Insensitization artificial 523  
Insulin diet and production of 1027  
International Congress on Industrial Medicine 524  
Students Conference 262  
Jet injection 830  
Kerosene poisoning in children 688  
Lead poisoning in children 609  
Lister Institute 485  
Liver disease fatty in children 213  
Lungs in diphtheria 260  
Malaria Pharmacology of antimalarial drugs 55  
Medical defence sixty years of 430  
— profession Remuneration of G P s 143—Deaths of doctors 212—Independent doctors 347—Threshold of practice 482  
Medicine as a woman's career 482  
Ménière's disease surgical treatment of 829  
Menstruation 1028  
Milk Safer to come 868—The Milk Bill 992  
Mushroom poisoning 393  
Naval medicine and research 35  
Neurosurgcons training of 365  
Nitroben mustard 304  
Nuffield College of Surgical Sciences 1072  
Nurses minority report on 718  
Nystagmus in pellagra 910  
Obstetric analgesia 607  
Oesophagus The short 144—Dilatation of 719  
Ophthalmology dozen of British 481  
Orthopaedics regional 751  
O Russia! O Mores! 991  
Pellagra nystagmus in 910  
Pelvic pain relief of 606  
Penicillin In experimental syphilis 261—Prolonging action of 653—Oral in children 867—By inhalation 1071  
Phagocytosis surface 687  
Phantom limb 262  
Pharmacology of antimalarial drugs 35  
Physiotherapy 1114

## Annotations (continued)

- Poliomyelitis virus in blood 1072  
 — acute in pregnancy 1071  
 Post gastrectomy syndrome 524  
 Psychotherapy for sexual offenders 752  
 Pulmonary arteriovenous fistula 910  
 — embolism stellate block in 608  
 Radium Commission 429  
 Rat blue fever 564  
 Retirement from office 81  
 Rheumatic myocarditis 751  
 Rockefeller benefactions 566  
 Ross Jubilee 82  
 Sebaceous nature of 911  
 Shellfish bacteriological examination of 33  
 Shock and hypertension new factors to 346  
 Silicosis vascular changes in 306  
 Skin Nodular defensive reactions of 144—Sensitivity to streptomycin 394  
 Sphenoid sinus 260  
 Stilbamidine toxicity of 653  
 Streptomycin skin sensitivity to 394  
 Sympathectomy for chronic leg ulcers 211  
 Syphilis experimental penicillin in 261  
 Tar Dangers of 394—Carcinogenic action of liquor picis carbonis 608  
 Temperature recording 991  
 Tetraethylammonium in vascular disorders 752  
 Thyroid enlargement and drinking water 794  
 Tuberculosis. Protecting children from 346—And voluntary action 1114  
 Typhoid carriers treatment of 305  
 Undulant fever chemotherapy of 1113  
 Vaccinia virus structure of 84  
 Vagotomy reports on 652  
 Vitamin A deficiency 718  
 — D in sarcoidosis 1070  
 Yeast live and dead 305

- ANSARI M Y Gangrene after scorpion sting 388 correspondence 498  
 ANSELL I Fatal case of myelitis after antituberc vaccine 338 (O)  
 Antibiotics from streptomycetes (leading article) 1112  
 Anticholinesterases in treatment of myasthenia gravis 160 891  
 Antihistamine drugs And radiation sickness (W M Court Brown and R B Hunter) 984 (O) correspondence 1120—And gastric secretion (annotation) 1028  
 — substances (Sir Henry Dale) 168 281 (O)  
 Antimony excretion of (annotation) 83 correspondence 440  
 Antiseptics Flavines and C T A B 967  
 Anuria Ureteric calculus causing (Nestor J S Nathan and Cyril Josephs) 713 (O)—Treatment of (D A K Black and S W Stanbury) 1101 (O) leading article 1111  
 Anxiety state. Treatment of in general practice (C A H Watts) 214 correspondence 398—CSF pressure in 640—Post traumatic 1047  
 Aortic coarctation with patent ductus arteriosus (H A Haxton and M L Thomson) 1062 (O)  
 Aorta thoracic permanent intubation of (annotation) 688  
 Aphasia 656  
 Appendicitis acute role of abdominal trauma in (W Rutherford Black) 424 (O)  
 Appendix perforated Residual pelvic abscess 926  
 Appointments 58 116 213 233 277 320 361 406 447 504 580 581 698 729 807 886 923 924 966 1003 1044 1045 1089 1101 1128  
 APURDOR R G BCG vaccination 106  
 ARMISTRONG Fergus Tribute to T G Maitland 578  
 ARMISTRONG J A gastric bezoar 995  
 Arsenic as cause of cancer (annotation) 912  
 Arsenicals and sulphonamides 321  
 Arterial disease 1048  
 Arteriosclerotic pseudobulbar palsy facial seborrhoea in (Frank A Elliott) 861  
 Arthritis osteo Injection treatment of 95—Of hip-joint (leading article) 142  
 — rheumatoid Early 322—Current remedies for 755—Course of (annotation) 912—Spontaneous rupture of muscle as complication of (G D Kersley) 942 (O) correspondence 1039—Treatment of advanced in few practical points (Trevor H Howell) 1029  
 Artificial limbs See Prosthesis  
 Aseptic technique (book review) 1023  
 Asphyxia of newborn Treated by rocking (F C Ely and the late N C Forsyth) 554 (O) correspondence 661 762 797 878 918 956 957 1079 1082—Lobeline and 1047  
 Aspirin keeping qualities of 236  
 ASSAULT M (and others) *Psychiatric et Psychologie* 140  
 ASSINDER E W Prevention of venereal disease 269  
 Association British 408—110th meeting at Brighton 654  
 — Hospitals Leagues of Friends 44

## ASSOCIATION BRITISH MEDICAL

- Academic workers 171  
 Annual Meeting President's Address 2—Leading article on 80  
 Annual Representative Meeting 35  
 B M A criticized (leading article) 392 correspondence 397 499  
 Committee on Care and Treatment of the Elderly and Infirm 401  
 Council Chairman elected 84  
 Gold Medal of the Association awarded 84  
 Hylfax Division Towards a lower paediatric mortality (Wilfrid Gursford) 969 (O)

## ASSOCIATION BRITISH MEDICAL (continued)

- Informal dinner 624  
 Loyal Address to the King 993  
 Popular lecture Accident and opportunism to medical research (Sir Henry Dale) 451 (O) leading article 479  
 Retirement of Dr J B Miller and Dr John W Bone (annotation) 81  
 Some points of debate (leading article) 80  
 Special Representative Meeting 110  
 Structure of B M A 49  
 Vice Presidents elected 84

## ASSOCIATION BRITISH MEDICAL PROCEEDINGS OF SECTIONS

- Section of Anaesthetics Anaesthesia for chest surgery 91 And Section of Obstetrics and Gynaecology Analgesia in midwifery 155 correspondence 356  
 Section of Anatomy and Anthropology Present position of primate anatomy 167—Present state of our knowledge of anatomy of the primates (F F Wood Jones) 629 (O) correspondence 763  
 Section of Child Health Neonatal mortality and morbidity 99—Nutritional study of German children 99 And Section of Radiology Malignant disease in infancy and childhood 162 (corrected) 236  
 Section of Dermatology Occupational dermatoses 97  
 Section of Diseases of the Chest Bronchial carcinoma (R C Brock) 93 737 (O) correspondence 799—Congenital heart disease 93—Surgery of congenital heart disease (Maurice Campbell) 669 (O)—Upper respiratory disease and certain lung conditions 157 correspondence 356 444  
 Section of Medicine Thorax and its derivatives in routine treatment of thorax (H P Hamsworth) 61 (O)—Summary of other papers 89—Macrocytic anaemias 153 And Section of Surgery Surgery in hypertension 152—Prognosis for surgically treated patients in continued hypertension (Reginald H Smithwick) 237 (O) leading article 258  
 Section of Neurology and Psychiatry Epilepsy of late onset 102—Senile deterioration 103  
 Section of Nutrition Importance of proteins 103—Protein deficiency and liver disease 104—Agerized flour 104—Significance of proteins in nutrition their particular importance during convalescence (D P Cuthbertson) 731 (O) leading article 749 correspondence 959  
 Section of Obstetrics and Gynaecology Problem of infertility 90—Third stage labour and its complications 156 See also Section of Anaesthetics  
 Section of Occupational Health Human relations in industry (Sir George Schuster) 100 505 (O) leading article 521 correspondence 875—Aviation medicine applied to civil aviation 165—Physiology of stratosphere flying 165—Fatigue in flying 166  
 Section of Ophthalmology Ophthalmic complications in obstetrics 101—Contact lenses 101—Significance and interpretation of refraction 166  
 Section of Orthopaedics Lesions of intervertebral disk 94—Injection treatment of osteoarthritis 95—Operative treatment of recent fractures 158—Treatment of acute haematogenous osteomyelitis 158  
 Section of Oto Rhino Laryngology Sphenoidal sinus 151—Poliomyelitis and tonsillectomy 151 correspondence 498—Sphenoid sinus (Arthur W Proetz) 243 (O) annotation 260 correspondence 497  
 Section of Pathology and Bacteriology Rhesus factor 95—Thymus in myasthenia gravis 96—Influenza meningitis treated with streptomycin 96—Cells deprived of glucose and oxygen 96—Electrophoresis 96—Acute and subacute hepatitis 159—Prophylaxis of virus infections 159—Visit to Strangeways Research Laboratory 160 (corrected) 236—Recent advances in our knowledge of the Rh factor (D F Cappelletti) 323 (O) leading article 344—Prophylaxis of virus infections with special reference to use of vaccines (C H Andrews) 1007 (O)  
 Section of Pharmacology Agents determining and influencing the functions of the pars nervosa of the pituitary (E B Verney) 119 (O)—Antihistamine substances (Sir Henry Dale) 168 281 (O)—Antidiuretic hormone 169  
 Section of Physiology and Biochemistry Recent work on proteins 96—Plasma and blood derivatives in treatment of burns 96—Protein hormones 97—Physiological basis of neuromuscular disorders (Sir Henry Dale) 160 889 (O) (corrected) 1048—Flocculation tests their chemical and clinical significance (N F MacLagan) 892 (O)  
 Section of Preventive Medicine Preventive medicine under the N H S Act 97—Acute poliomyelitis 161—Morbidity statistics 161  
 Section of Radiology Radiodiagnosis 163—Radiotherapy 164—Coeliac disease (Wilfrid Sheldon) 594 (O) See also Section of Child Health  
 Section of Surgery Tuberculous adenitis 89—Carcinoma of breast and its treatment (Sir Cecil Wakeley) 154 (corrected) 450 631 (O) correspondence 759 See also Section of Medicine
